Operating Temperature	< 120°C	< 100°C	150–200°C	600–700°C	500–1000°C
Electrical Efficiency	60% (direct H ₂) 40% (reformed fuel)	60%	40%	50%	60%

having an operating temperature 1000°C (Baur and Preis, 1937). Most of the SOFCs operate at very high temperature of 800–1000°C, which causes material degradation and, as a result, incur higher maintenance cost. Therefore, researchers, especially in last two decades, focused on developing intermediate (500–800°C) range SOFCs (Mahato *et al.*, 2015; da Silva and de Souza, 2017). The main advantages of SOFC are the lower cost compared to solar and wind energy, less greenhouse gas emission, durability, noise-free power generation, direct conversion of chemical energy to electrical energy and reliability. During 2004–2006 alone, the cost of fuel cell unit reduced from \$8000/KW to \$4800/KW (Shaikh *et al.*, 2015; Shahid Rafique *et al.*, 2018). However, more attention in research is now given to further reduce the unit cost of SOFC by developing new and efficient electrode materials.

Starting from Ni-cermet anodes and LSM (LnSrMnO₃) cathodes, a wide range of ceramic materials has been explored for enhancing the efficiency and lowering the working temperature of Solid Oxide Fuel Cells. Porosity and its characteristics play a major role for efficiency enhancement of SOFC. When porosity is > 25%, gas phase becomes fully in contact with the Triple Phase Boundary (TPB). For effective performance, optimum porosity of the electrodes are estimated to be 36%–48% (Bertei and Nicolella, 2011; Yang *et al.*, 2015). Pore size and distribution are also controlling factors of gas flow inside the electrodes.

Working Principle of SOFC

The main components of SOFC are porous electrodes (anode and cathode) and solid electrolyte that is sandwiched between the two electrodes. Both electrodes and electrolyte are ceramic material. Porous anode and cathode are electronic conductors and the

Fig. 5 Schematic diagram of SOFC working principle having (a) oxide ion conducting electrolyte, and (b) proton conducting electrolyte.

Table 4 Evolution of nanoporous anode materials

Material	Processing method	Porosity	Operating temperature (°C)	Electrolyte/Cathode	Maximum power density (mW/cm ²)	Ref.

electrolyte is dense, impervious and ion/proton conductor. Anode and cathode are externally connected. The anode side (also called Fuel side) receives H₂, hydrocarbons or methanol as a fuel, oxidizes them and generates electrons that flow through external circuit. Oxygen (or oxidant) is reduced at the triple phase boundary of cathode, gas and electrolyte. Generated oxide ions diffuse through ion conducting electrolyte via vacancy hopping mechanism at high temperature (800–1000°C). High temperature enables and makes the electrolyte ion conductor. At the anode-electrolyte-gas triple phase boundary (TPB), H₂ and O₂⁻ ions react to form H₂O (Mahato *et al.*, 2015; Shaikh *et al.*, 2015; Kee *et al.*, 2008). A schematic diagram of SOFCs operating principle is presented in Fig. 5.

Table 5 Evolution of nanoporous cathode materials

Material	Processing method	Porosity	Operating Temperature (°C)	Maximum Power Density (mW/cm ²)	Ref.
Sm _{0.2} Ce _{0.8} O _{1.9} (SDC) and Sm _{0.5} Sr _{0.5} CoO ₃ (SSC)	Spin coating	Small, inter-connected pores	600	300	(Chen <i>et al.</i> , 2011)
LSM (La _{0.8} Sr _{0.2} MnO _{3-δ}) cathode supporter and LSM-Sm _{0.2} Ce _{0.8} O _{2-δ} (SDC) cathode functional layer (CFL)	Slurry spin coating	23%–33%	850	580	(Chen <i>et al.</i> , 2012)

(La _{0.8} Sr _{0.2}) _{0.95} MnO ₃ (LSM95)	Tape casting	33.76%–45.50%	750	325	(Wang <i>et al.</i> , 2013b)
La _{0.6} Sr _{0.4} Co _{0.2} Fe _{0.8} O ₃ and Gd-doped ceria (LSCF-GDC)	Screen printing, sintering 1200°C	Highly porous	750	0.38–0.83 Ωcm ² (polarization resistance)	(Liu <i>et al.</i> , 2013)
Double perovskite SmBaCo _{2-x} Ni _x O _{5+δ} (SBCN _x) (x = 0–0.5)	Screen printing	Porous cathode	800	536	(Xia <i>et al.</i> , 2016)
Sm _{0.5} Sr _{0.5} CoO _{3-δ} (SSC)	Electro spinning	Very porous nano fiber cathode	700	1090	(Chang <i>et al.</i> , 2015)
NdBaFe _{2-x} Mn _x O _{5+δ} (0.0 ≤ x ≤ 0.3)	Citric acid- nitrate process, sintering 1200°C	Porous cathode	500–700	453	(Mao <i>et al.</i> , 2015)
Sr _x Co _{0.7} Nb _{0.1} Fe _{0.2} O _{3-δ} (SCNF, x = 0.95 and 1)	Screen printing	Moderate porosity	700	208–180	(Ding <i>et al.</i> , 2017)

Materials Used in SOFC

Anode

Anode is the most important component of SOFC where the oxidation of fuel takes place. An anode must possess enough porosity, electrical conductivity and chemical compatibility with electrolyte at operating temperature. The following reaction takes place at anode-

Electro-catalytically active and high electronic conductivity makes cermet based anodes, e.g., Ni-YSZ (8 mol% Y₂O₃ and ZrO₂), most commonly used anode material. However, some limitations associated with Ni-YSZ anode at the SOFC operating temperature are Ni sintering, deposition of Carbon (from hydrocarbon fuels) and Sulfur poisoning. To overcome these drawbacks of Ni based cermets, many studies have been conducted for increasing the stability, durability and electrical conductivity of anodes like: Ni-YSZ anodes modified with Ag (Wu *et al.*, 2016), Al₂O₃ (Song *et al.*, 2016); Ni-SDC (Chen *et al.*, 2008a), Ni-GDC (Fu *et al.*, 2010), Ce based cermets (Ce_xZr_{1-x}O₂) (Kearney and Baker, 2012), LnSTMperovskites (Ln=La, Nd, Sm) (Jeong *et al.*, 2015), PbMO₃ (Pr_{0.5}Ba_{0.5}MnO_{3-δ}) (Sun *et al.*, 2016) etc. Double perovskite based materials have been reported as well and claimed to be exhibited longer life and highest efficiencies. Various anode materials along with their efficiency and porosity are listed in Table 4.

The efficient anode must contain the following chief characteristics:

- High electrical conductivity at operating temperature
- Sufficient electrochemical and catalytic activity for the oxidation.
- Minimal CTE mismatch with other adjacent cell components
- Fuel flexible and able to tolerate carbon deposition and sulfur poisoning.
- Chemical and thermal stability.
- Sufficient mechanical strength to withstand mechanical stress at high operating temperature.
- High porosity (20%–40%) for smooth fuel migration and the reaction product release (Singhal, 2000).

Cathode

Cathode is a porous electrode where reduction of O₂ takes place. Materials selection for cathode should be such that it possesses high electronic conductivity, stability and it remains unreactive to electrolyte materials at high operating temperature. In cathode, the following reaction takes place:

$\text{Ln}_{1-x}\text{Sr}_x\text{MnO}_3$ (LSM perovskite) is used as most common cathode material (Chen *et al.*, 2012). Researches have been conducted on LSM/GDC cathodes (Ahmed *et al.*, 2014), $\text{LnBaCoO}_{5+\delta}$ ($\text{Ln} = \text{La, Pr, Nd, Sm, Gd, Y}$) (Xia *et al.*, 2016) and NBCO ($\text{NdBaCu}_2\text{O}_{5+\delta}$) (Kong *et al.*, 2015) cathodes along with $\text{A}_2\text{BO}_{4+\delta}$ ($\text{A} = \text{rare-earth material, B} = \text{Cu, Fe, Ni}$) based composite cathodes (Ferkhi and Ahmed, 2016; Kolchugin *et al.*, 2016). Dependence of Maximum Power Density of SOFC on cathode material and porosity is presented in Table 5.

For an efficient operation of SOFC, the cathode should possess the following functionalities:

- High electronic conductivity (preferably more than 100 S/cm in an oxidizing atmosphere)
- Minimal or no CTE mismatch with other components of the cell
- Chemical compatibility with electrolyte and interconnect materials
- Porous structure to allow fast diffusion of O_2 from cathode to cathode-electrolyte interface
- High ionic conductivity
- Good oxidizing stability
- High catalytic activity during oxygen reduction reaction (ORR)

Conclusions

In this review, the prospect of porosity in nanostructured materials have been summarized particularly for solar and fuel cells. For future photovoltaic research, Porous Si (PSi) can be simultaneously integrated as antireflection coating and Bragg reflector with Si solar cell to improve the overall cell efficiency. Besides, reusability of substrate can highly reduce the cost of solar cell fabrication if Porous Si (PSi) is used as wafer. The use of PSi as substrate for thin film solar cell like Ge, GaAs, GaN requires more focus as it may revolutionize many current research trends which are not limited to solar cell applications. For Dye Sensitized Solar Cell (DSSC), morphology design like Nanorod/Nanosphere, Nanowires/Nanodonuts along with combination of different materials in heterostructured Photoanode has been seen enhancing the overall cell efficiency of DSSC in some recent research. Considering fuel cells, characteristics of pore in electrodes are controlling factor for better performance and efficient Solid Oxide Fuel Cell (SOFC). Among the three components of SOFC, both electrodes are based on porous materials and emphasis has been given by the researchers mostly for the development of electrodes with controlled porosity in order to enhance the durability of electrodes and lowering the operating temperature of SOFCs.

Introduction

The region of Kosovo and Metohija is rich in mineral resources. Its energy resources and non-ferrous metal resources represent a considerable potential for the overall development. Not all parts of Kosovo and Metohija are equally rich in mineral raw materials. Mineral deposits represent a true natural basis for development of industry, i.e., economy as a whole. Some of the most important resources are lignite, minerals of lead, zinc, silver and gold, silicate minerals of nickel and cobalt, iron – bauxite, manganese and magnesite. Moreover, there are also significant amounts of non-metallic, industrial minerals and geological construction materials. Specified mineral resources and their rational exploitation combined with good management approach represent a solid basis for quick and sustainable economic and social development.

All kinds of existing resources that a country has at its disposal make up a foundation for planning and implementation of development and energy strategy. Each of the specified resources has bigger or smaller resource potential, but planning and strategic exploitation are insufficient. That is why it is necessary to define accurate sector policies and strategies and to select proper mechanisms for their implementation. Regarding Serbia, this goal is extremely difficult to realize at this moment because the region of Autonomous Province of Kosovo and Metohija is a UN protectorate and subject to a Resolution 1244. In fact, at this moment Serbia as a country does not have any mechanisms that could be used to protect those natural mineral resources from exploitation. On the other hand interim institutions in Kosovo and Metohija are doing everything in their power to use those resources for their own development. Pursuant to any natural and international law, including resolution 1244, mineral resources of Kosovo and Metohija should stay in Serbia. Since Serbia has been exposed to double standards by the developed Western countries that recognized unilateral independence of AP of Kosovo and Metohija, the so called independent state of Kosovo was given the opportunity to exploit all of the mineral resources (Figs. 1–3).

Lignite Reserves in Kosovo and Metohija

Lignite reserves are by far the most abundant among mineral resources in the region of Kosovo and Metohija. There are still no accurate estimates of the amount of lignite in the region of Kosovo and Metohija. According to Serbian scientists, [Nikolić and Dimitrijević \(1990\)](#), lignite reserves in Kosovo, Metohija and Drenica basin are 7.35 billion tons (Bt). Out of the specified amount, only 1.6 Bt in Kosovo basin are economically exploitable, while 4.8 Bt are non-exploitable (as well as 0.7 Bt in Metohija basin and 0.25 Bt in Drenica basin). As for the thickness of exploitable seam, it is the biggest in Kosovo basin (24–60 meters), then in Metohija basin (36–40 m) and then in Drenica basin (5–18 meters). Only in Kosovo basin is the thickness of overburden smaller than thickness of lignite seam. In Metohija basin that overburden thickness is 2.5 times bigger than thickness of lignite seam. Bigger overburden thickness implies more expensive lignite exploitation and, consequently, smaller profit, i.e., lignite-based wealth of the region. The average overburden to lignite ratio in Kosovo basin is 1.3 m³/t and in Metohija basin 2.4 m³/t.

On the one hand it is positive that there are large amounts of lignite, but on the other hand the negative factor implies high contents of moisture and ash (because of gangues) and increased contents of toxic microelements of Ni and Cr in lignite that are enriched in thermal power plants smoke, so this lignite represents an important but low-budget raw material for exploitation and production of electric energy that pays off only with minimal transport or exploitation on the spot ([Karamata et al., 2006](#)).

According to the data of the interim institution, Ministry of Economic Development, the estimated lignite resources on the entire territory of Kosovo and Metohija are 12.4 Bt ([Anon1, 2012](#)).

In Rainer Hengstmann's report from 2004, the Independent Commission for Mines and Minerals of Kosovo, which was regulated by UNMIK, published that the World Bank estimated the mineral reserves of Kosovo to be worth 13.5 billion euro. The most significant resource is lignite, with geological reserves of about 15 billion tons (Anon2).

This estimate is in line with the estimates by experts from the Faculty of Mining and Geology in Belgrade who also estimated that the lignite potential in Kosovo would be sufficient to supply two thermal power plants and to provide electricity production in a hundred-year period which, according to the estimate of our Ministry of Mining and Energy from 2009, equals the value of 100 billion euro. Therefore, a major part of lignite reserves in the Republic of Serbia (over 76%) is located in Kosovo-Metohija basin (Anon3, 2015) (Tables 1–3).

In one of its reports, the United States' CIA says that, according to international standards, Kosovo is worth 500 billion dollars (estimated reserves of coal, natural gas and metal), and the remaining part of Serbia with Vojvodina only about 200 billion dollars. In line with one study mentioned in that report, the USA experts estimate that in Serbia there are coal reserves for maximum 35–40 years, while in Kosovo there is coal for as much as 16 centuries. Another study estimates that reserves of coal in Serbia are sufficient for 60 years, and in Kosovo for 200 years. They point out that the value of localities of seven strategic ores (lead, zinc, silver, nickel, manganese, molybdenum and boron) was estimated to as much as 1000 billion dollars (Anon4).

It could be concluded that there is enough lignite to last us more than one century, even with the increased exploitation. Importance of lignite for the region of Kosovo and Metohija is supported by the fact that the share of lignite in total electric energy production is about 97%, while hydroelectric power plants account for 3% of production (Anon5, 2013).

Table 1 Lignite reserves in Kosovo and Metohija

Basin	Reserves		
	Geological	Balance reserves ^a	Off-balance reserves ^b
Kosovo	10.09	8.77	1.31
Metohija	2.24	2.04	0.19
Drenica	0.10	0.07	0.03
Total	12.44	10.89	1.54

^aBalance reserves are reserves in which thermal power of coal exceeds 5450 kJ/kg.

^bOff-balance reserves are reserves in which thermal power is smaller than 5450 kJ/kg.

Note: Anon1, 2012. Privremena institucija samoupravljanja – Ministarstvo ekonomskog razvoja, Strategija za rudarstvo Republike Kosovo od 2012–2025. Priština, p. 14.

Table 2 Thermal power plants in the region of Kosovo and Metohija

Thermal power plant name	Thermal power plant Kosovo A		Thermal power plant Kosovo B		Thermal power plant Kosovo C	
Block	Block 3	Block 5	Block 1	Block 2	Block 1	Block 2
Status	existing	existing	existing	existing	new ^a	new ^a
Operating since	1970	1975	1983	1984	2018	2018
Capacity MWe	200	210	339	339	300	300

^aBeginning of operating of new plants is based on estimate.

Note: Holland, M., 2016. Health and Environment Alliance, Tehnički izveštaj: Uticaji termoelektrana na ugalj na zdravlje na Zapadnom Balkanu, mart.

Table 3 Annual numbers of cases of premature death in Europe that can be ascribed to any plant operating with capacity adjusted to loading factor

	Sulphur-dioxide	Nitrogen-dioxide	PM2.5 ^a	Total
Kosovo A, block 3	17	11	21	49
Kosovo A, block 5	36	22	45	103
Kosovo B, block 1	53	38	18	109
Kosovo B, block 2	53	38	18	109
Total	159	109	102	370

^aPM2.5, fraction of "dust" whose diameter is smaller than 2.5 µm.

Note: Holland, M., 2016. Health and Environment Alliance, Tehnički izveštaj: Uticaji termoelektrana na ugalj na zdravlje na Zapadnom Balkanu, mart.

With the estimated lignite value of about 12(Anon6)–15(Anon4) Bt, Kosovo ranks third (after Germany and Poland) in Europe, and fifth in the world regarding established lignite reserves.

Exploitation of Lignite in Kosovo and Metohija

The main energy sources in Kosovo are located in two major lignite basins known as “Kosovo” basin and “Metohija” basin, with usable lignite deposits (Avidiu *et al.*, 2009). Kosovo basin covers the area of 274 km², and Metohija basin the area of 49 km², while the other basins cover 5.1 km² (Bojaxhiu *et al.*, 2009).

The first systematized data on lignite exploitation, i.e., small-scale lignite mining in Kosovo basin, dates back to 1922. More extensive lignite production started with the opening of open-pit mines Miras (1958) and Belacevac (1969) and by application of modern excavators (diggers). Lignite exploitation in those open-pit mines, that represented one collective exploitation area, ended in 2012. Annual production capacity in both mines was 28,000,000 m³ of gangue (solid mass) and about 17,000,000 tons of coal. Since 2010, coal has also been exploited from the so called “New mine” (southwest of Sibovac), and this mine is in the final phase of development.

Among lignite fields in Kosovo and Metohija, Field Sibovac is the largest exploitation reserve. It comprises approximately 330 metric tons of exploitation reserves and has the smallest portion of overburden. Field Sibovac covers the area of 16 km², with maximal depth of 3.8 km and length of about 6 km. In addition to the new mine, Sibovac Southwest, in which lignite is already being exploited, the plan is to start with exploitation of the southeast part of Sibovac field that has been examined, as well as with two alternative fields: Field D and Field South Sibovac (Kosovo Power Project).

In the figure above, potential mining fields of lignite can be observed (Field Sibovac, Sibovac Southwest, Field D and Field South), as well as mines in which exploitable lignite has been exhausted (Miras and Belacevac).

It is important to mention that the prospects of finding new coal localities are very favourable and realistic, due to good geological prerequisites. There are indications that there is coal in many other locations, especially in the south part of the Pec land, in the part of Djakovica and Prizren. Also, one of potential locations is the Neogene basin of Kriva Reka that represents a tectonic basin formed in the cross-border area of a Dardani massif on the east and Vardar zone on the west, whereby the thickness of coal seam in this region reaches 5 m. It would be reasonable to expect intensification of explorations aiming at a discovery of new lignite localities.

Taking into account the specified lignite amounts, it would be reasonable to expect that lignite, as an energy generating product, will continue to be the main source of energy in Kosovo and Metohija. With that in mind, it is necessary to:

- Follow up the developments, in our neighbouring countries and worldwide, related to technology of clean combustion of lignite intended for increased utilization in industry and heating plants and economically justifiable from social and environmental aspect;
- Intensify geologic investigation in order to develop the strategy of lignite exploitation planning;
- Apply economically and environmentally justifiable procedure of lignite refinement in order to comply with modern technological solutions for utilization of lignite in industry and in mass consumption (Mitrović and Kojić-Lekić, 2006).

Thermal Power Plants in the Region of Kosovo and Metohija

In the region of Kosovo and Metohija there are two thermal power plants: “Kosovo A” and “Kosovo B”. Thermal power plant “Kosovo A” consists of five working blocks known as A1, A2, A3, A4 and A5. Block A1 of this thermal power plant was put into operation in 1962 with the power of 65 MWe; A2 in 1965 with the power of 125 MWe; A3 in 1970 with the power of 200 MWe; A4 in 1971 with the power of 200 MWe and A5 in 1975 with the power of 210 MWe. At the moment blocks A3, A4 and A5 are functional. According to the current production plan, two blocks are in use (A3 and A5), while one of them (A4) is a hot reserve because of their low readiness and age. Blocks A1 and A2 are non-functional and are without defined status and according to the current plans they will remain like that until the end, when their decommissioning is expected. The whole thermal power plant “Kosovo A” is in bad condition and is considered to be the worst single pollution source in Europe. Interim institutions in Pristina plan to decommission it, but it cannot be done until sufficient amount of electricity has been provided, which is not feasible at the moment. Annual electric energy production from thermal power plant Kosovo A is around 1500 GWh (Anon7).

In thermal power plant “Kosovo B” Block 1, built in 1983, is active (339 MWe) and so is Block 2, constructed in 1984 (339 MWe), and they are both in need of rehabilitation after being operational for 35 years in order to be aligned with environmental standards of the European Union.

The total capacity of these two thermal power plants (Kosovo A and Kosovo B) amounts to 988 MWe. The plan is to have the thermal power plant Kosovo C, with block 1 (300 MWe) and block 2 (300 MWe), built and put into operation until the end of 2018 (Holland, 2016).

According to the plan, thermal power plant Kosovo A will be decommissioned by the beginning of 2023, when thermal power plant Novo Kosovo, currently under construction, is expected to be put into operation, and after that thermal power plant Kosovo B will undergo rehabilitation (Anon8, 2017).

Environmental Pollution by Thermal Power Plants in Kosovo and Metohija

In this part we shall discuss the environmental pollution related to air emissions of pollutants, created by lignite combustion in thermal power plants in Kosovo and Metohija. As it was already mentioned, in Kosovo and Metohija 97% of electric energy production is based on lignite exploitation. The first step in this process is procurement of raw material for further processing and transformation (Mikić *et al.*, 2017). Large amount of lignite makes possible a certain level of energy independence on the one hand, while on the other hand negative effects of reliance on lignite must be taken into account. Thermal power plants "Kosovo A" and "Kosovo B" operate according to outdated environmental standards, thus producing high emissions of harmful gases which, consequently, greatly affect the environment and human health. In order to reduce harmful gases emission and, consequently, their negative influence, thermal power plant "Kosovo A" needs to be shut down (which is planned to be done until the end of 2023), while thermal power plant "Kosovo B" needs to be improved in order to comply with new legal requirements based on standards that are much stricter than those that currently apply to the existing thermal power plants. Those new standards have been defined by Industrial Emissions Directive (IED) of the EU (European Parliament, 2010).

Regardless of the stricter standards, we have to be aware that the negative consequences cannot be avoided 100%, but at least they can be reduced to a minimum that will not affect environment and human health severely. If the quality of air in a region complies with the requirements, it does not mean that people who live in that region are fully protected from the influence of air pollutants from a certain source. Estimate of pollutants' influence on environment represents a subjective attitude and does not imply the absence of that influence. There are numerous studies of the influence of air pollutants on health, both in our country and worldwide, according to which the risks are not limited to areas in the imminent surrounding of the plants or other combustion objects, but extend to larger areas, sometimes several hundred kilometres away, because the said particles are transmitted by wind and end up deposited on the ground. These harmful substances bring about enormous environmental problems and are a threat to human life and human health (Papadopoulos *et al.*, 2011). What can be done to reduce the harmful consequences of lignite combustion in thermal power plants is to adjust them to the specified standards and to increase the competitiveness of renewable technologies for energy production in relation to exploitation and utilization of lignite in thermal power plants.

By combustion of lignite in thermal power plants harmful particles (sulphur-dioxide SO₂, nitrogen-dioxide NO₂ and particulate matter (PM)) are emitted, which causes pollution of air. Influence of SO₂ and NO₂ is connected not only with exposure to pollutants in the form in which they are emitted, but also to products of their reactions, since they react with other pollutants in the atmosphere forming the aerosol (ammonium-sulphate and ammonium-nitrate in particular) that contributes to the overall particulate loading of air. Nitrogen-dioxide also reacts with volatile organic compounds in the presence of sunlight which results in production of increased levels of ozone, the other pollutant that is considered to be a threat to health (Holland, 2016). Other dangerous substances emitted from flue-gas stacks of coal thermal power plants are heavy metals, e.g., mercury, and persistent organic pollutants such as dioxins and polycyclic aromatic chemicals. High emissions of mercury from lignite-fired thermal power plants raise special concerns about the health of children (Health and Environment Alliance HEAL, 2014).

The influence of air pollutants on health includes death due to respiratory and heart problems, bronchitis, hospitalization and many other negative effects. Exposure to open air contamination is associated with a large number of acute and chronic health conditions, ranging from irritation to death (Anon9, 1996).

The table below shows the annual number of cases of premature death in Europe that can be ascribed to thermal power plants in Kosovo and Metohija.

The latest data, published in HEAL report, show that the influence of harmful particles produced by lignite combustion in thermal power plants on the annual level round the European Union resulted in over 18,200 cases of premature death, around 8500 cases of chronic bronchitis, and over 4 million days of absence from work. Economic costs of coal combustion impact on human health in Europe are estimated as 42.8 billion euro per year (Anon10, 2013).

In addition to negative health consequences, harmful effects caused by air pollution by lignite-fired thermal power plants have financial consequences as well, regarding both population and the state. Monetization of the influence of lignite combustion in thermal power plants is related to several factors: additional health care costs resulting from hospitalization, increased consumption of medicines etc.; lost productivity of workers who take sick leaves because they themselves are ill or to take care of ill family members and; loss of what is labelled as "usefulness" or "pleasure" in economic literature due to pain, suffering and reduced life expectancy (Holland, 2016).

Due to everything aforesaid, air pollution brought about by lignite combustion in thermal power plants is being increasingly acknowledged as a considerable threat to public health.

Conclusion

If a country wishes to plan and realize the energy strategy, it should possess energy resources. It is typical that countries with larger reserves of energy resources have a higher level of energy independence.

The actual lignite reserves in Kosovo and Metohija are still not known as a fact. All lignite localities in Kosovo and Metohija are still not sufficiently known and have not been sufficiently explored. What we do know at the moment is that those reserves are so immense that owing to them Kosovo ranks third in Europe and fifth in the world regarding the amount of lignite.

Big world players have joined the battle for exploitation of Kosovo resources. In addition to American companies, German, British, French and Turkish companies are also interested in investing into mining localities and exploitation of natural resources of Kosovo. It is an interesting fact that the American company "Envidity", run by a retired NATO general Wesley Clark, asked for a licence to explore coal reserves in order to be able to produce synthetic oil from coal, with the production plan of 100,000 barrels of oil per day.

Lignite is the main energy source in Kosovo and Metohija. Its share in total electric energy production is about 97%, while hydroelectric power plants account for only 3% of production. Due to large amount of lignite reserves, the situation is likely to remain the same in the period to come. According to the European Association for Coal and Lignite (EUROCOAL), coal will continue to be important as a factor among energy generating products for a long time for the purpose of electric energy production whose increasing needs are definite and will continue to grow. In order to meet the need for electric energy, it is necessary to modernize the existing and to apply new, technologically innovative processes of obtaining lignite as an energy generating product.

Currently, there are two active thermal power plants in the region of Kosovo and Metohija: thermal power plant "Kosovo A" (blocks A3, A4, A5) and thermal power plant "Kosovo B" (block 1, block 2). These two lignite-fired thermal power plants emit thousands of tons of harmful pollutants every year, thus contributing to air pollution considerably and not only in the region of Kosovo and Metohija, but in the Balkans region and farther, because the pollutants are transmitted by air to a greater distance. Operating of the said thermal power plants is characterized by outdated environmental standards, which contribute to creation of high levels of emission of pollutants that have numerous negative effects on the environment and human health. Therefore, it is necessary to revise the energy production plans in order to reduce reliance on lignite and exclude it in the end and in order to increase investments into renewable energy sources.

New Educational Models to Train Engineers and Executives On Eco Friendly Technologies, Products and Sustainability Policies

Emmanuel Koukios, Lazaros Karaoglou, Sofia Papadaki, Dimitrios Koullas, and Nikolaos Kourakos, National Technical University of Athens, Athens, Greece

© 2020 Elsevier Inc. All rights reserved.

Rationale and Background

The deployment of large-scale renewable resource applications, viewed as a major shift towards the “greening” and sustainability targets, can only be based on the existence of an adequate human capital, which requires efficient information transfer processes, typically associated with education and training schemes. Nevertheless, the complexity and fragmentation of the renewable energy and materials utilization field itself makes such information processes cumbersome and ultimately inefficient, i.e., fluctuating between shallow empiricism and deep theorizing.

In this paper we will survey the 20-long years’ experience of the Bioresource Technology Unit (BTU) of the National Technical University of Athens (NTUA), Greece, in various types of engineering and technology management education and training actions, ranging from the undergraduate and graduate level all the way to lifelong learning schemes, aiming at generating lessons and tools for broader use.

Rationale

There exist several main characteristics of our present era, which should be seriously considered while organizing the education of engineers and executives on “greening”-related subjects and disciplines:

- *The short life cycle of the new knowledge* (Meister, 1998): The knowledge production rate has been accelerated significantly during the last couple of decades thanks to the info-, bio- and more recently nano-based technology revolutions (Gronau *et al.*, 2004) Although a solid background of basic scientific knowledge is always necessary, the current engineering and management portfolios should include specific skills which will facilitate their access to the new knowledge and to the innovation production and use mechanisms.
- *The need for multidimensional sustainability* (Steinbock *et al.*, 2011): The more traditional techno-economic studies carried out for a spectrum of industrial or service sector processes and products should be also increasingly coupled with eco-societal sustainability assessment studies.
- *From process to product and service design*: The saturation of process engineering needs press for a major shift in the global engineering market, where the product, service and system design skills should lead to the desired outlets, especially in the developed economies.

Background

The following is a list of the experimental courses or programs with an innovative structure, form and/or content, all carried out for the several recent years? by the Bioresource Technology Unit of NTUA:

- A sequence of three *Green Engineering* design courses for senior NTUA Chemical Engineering students – as part of the Organic Industries option (elected);
- A freshman NTUA Chemical Engineering elective course aiming at an Introduction to *Information and Knowledge Society* for young engineers;
- A *Bioenergy* course for the post-graduate NTUA’s program on Energy Production and Management – as part of the Renewable Energies option (elected);
- A week-long Advanced Summer School on *Biobased Technologies* for European and Indian Young Researchers, organized by NTUA;
- A training program on *Technology Management* organized by NTUA – a long version for business persons, and a short one for PhD-level researchers; and
- A Master-level program for re-training executives on *Sustainability Policy and Practice*, also organized by NTUA and taking place during summers on Greek islands.

Teaching Approaches and Methodologies

An overview of the long list of innovative elements which have been introduced in the above educational and training schemes follows:

- Project- and group-based learning;
- Individual learning through projects different for each student;
- Balanced group and individual learning activities;
- Thematic character of yearly course runs; e.g., this year, projects on wastes; next year, projects on “green” chemicals;
- Preparation of short “strategic” executive reports, with a set table of contents;
- Oral presentations by groups and individuals under strict time constraints;
- Molecular and other fundamental approaches of the problems addressed;
- Quantitative vs. descriptive solutions to problems, with emphasis in design;
- Product innovation combined with process, service, and system ones;
- Simulation games, e.g., to consider and model stakeholders’ involvement;
- Laboratory work planned and executed by students to fill gaps in their work;
- Optimal use of web-based sources of information and learning methods;
- Feasibility and sustainability criteria systematically searched and applied;
- Courses/programs evaluated by students, educators and other participants, with results communicated to class and discussed on the course final day.

Special attention was given to the exploratory use of a number of Web 2.0-based tools, with emphasis on their smooth potential acceptance by students, educators and administrators; in particular (Kourakos, 2018):

- *Learning styles*, as a class mapping tool for optimal education effects;
- *Mind maps*, as an analysis and synthesis tool especially for complex training landscapes;
- *Wikis*, involving the creation, collaboration and operation of *scoops* by trainees; and
- *Content curation* as a key collective action by all agents of the training processes.

Undergraduate Engineering Courses

Several innovations were integrated to the teaching methodology of the above mentioned four courses in order to provide the necessary tools to the students of NTUA Chemical Engineering School for dealing with the above presented challenges:

- Project based learning through real-life applications (Ribeiro, 2011);
- Multi-disciplinary approach through interactive lectures and experts tutoring on specific project related topics;
- Consecutive semesters coordination for an in-depth optimization of sustainable solutions;
- Shift from process to product design;
- Integration of the new concept of “molecule domestication”;
- Use of multiple research techniques from desk research to experimental data production;
- Design of student experiments according to the needs of each specific project;
- Overviews of the specific scientific fields according to the specific student project needs, provided from a wide spectrum of applications in organic chemical industries;
- Student feedback through evaluation questionnaires, the outcomes of which are used in the continuous improvement process of the courses.

An additional innovation which was integrated into the undergraduate educational process consisted in the profiling of the student learning style that took place in the beginning of each course cycle. According to Felder (Felder and Silverman, 1988), students learn in many ways: by seeing and hearing; by reflecting and acting; by reasoning logically and intuitively; by memorizing and visualizing. However, teaching methods do not take that variety into account and, as a rule, the results of this mismatching have a really heavy negative impact on the efficiency of the whole learning process. Therefore, a fine tuning step guided by the outcomes of the student learning profiling took place, thus affecting the teaching methodology which was followed for each individual group of students in order to minimize the mismatch.

Post-Graduate Technology Courses

The “Biomass” course, which is offered within the frame of the post-graduate program “Energy Production and Management” of NTUA, concerns a more diverse audience, since the attendants of the program, although predominantly engineers, come from different disciplines. The innovative dimensions of the educational methodology applied can be summarized as follows:

- Personalized student projects, which cover the whole range of biomass-to-biofuels and bioenergy applications;
- Region-specific sustainability assessment of each examined application chain;
- Holistic, system approach of the optimization process, instead of the independent process optimization approach;
- Discussion of the non-technological and non-economic dimensions of the feasibility and sustainability assessment; i.e., assessment of social acceptance and environmental impacts;

- Encouragement of the use of Web 2.0 tools for synergistic and group work, which will facilitate the dissemination of the knowledge among the course attendants, as well as the wider community of the bio-based economy;
- More specifically, a digital content curation platform was developed in order to give the opportunity to course attendants to publish online material and to have useful interactions among the web society.

In addition to the above innovative elements, a decision-making simulation game was introduced to this course, inspired by a then ongoing real-life biomass-based energy project. The students, in groups, are asked to represent specific stakeholder categories and to rank their priorities, as a key step towards reaching a final decision on the feasibility and sustainability of the particular project. The framework of the most recent respective project assigned to the students is shown in the following [Box 1](#) (Karaoglanoglou, 2017).

Box 1 Decision making simulation game – Assessment of the stakeholder involvement in a typical Biomass-to-Energy rural project

The municipality of Thermi, in Salonika, is in the process of evaluation of a project according which a biomass gasification unit will be installed in the region. The unit will process non-hazardous residual biomass for the production of Synthesis Gas, which will be used for power generation (498 kWel).

Scope of project: Electricity generation, which will be sold to the Power management authority according to the existing legislative framework.

Feedstock: Wood chips.

Capacity: 5000 t/a wood chips (or 15 t/d), which will be supplied by the local and/or international market, according to the current market prices.

Overall investment: 750.000 Euro to be financed 25% by own sources, and 75% by a loan.

Location: The plant will be installed on a land area of 4800 m², which is located on the North of the National road of Thessaloniki-Polygyros.

For the initial feasibility assessment of the specific project, a stakeholder meeting will be organized, where all the major stakeholders will be represented. More specifically: (a) Biomass producers handling trimmings and other agro-based biomass sources of the region; (b) Companies or individuals managing municipal biomass sources; (c) Bioenergy (gasification) industry; (d) Electricity distribution company; (e) Local community; (f) Local government; (g) Central government; (h) Other stakeholder to be decided following a discussion in the class.

The student groups were asked to represent each of the interest groups during the workshop and to rank its priorities in the following decision-making criteria (where 1: the most important criteria and 9 the least important one), justifying in the meantime their decisions.

Decision criteria: (1). Return on Investment; (2). Annual revenues; (3). National economy; (4). Regional/Local economy; (5). Application of new/innovative technologies; (6). Employment; (7). Environment; (8). Political and institutional benefits; (9). Other criteria.

Until the meeting date the students should:

- (1) Rank their decision priorities, first on a personal basis and then as specific stakeholder group;
- (2) Clarify under which conditions they would be absolutely positive or supportive, absolutely negative or just reluctant about the realization of the project; and
- (3) Assess the potential alliances which can be built with other stakeholder groups.

Life-Long Executive Education

The specific Training Workshop for European and Indian Researchers took place within the framework of the EU-funded FP7 project "SAHYOG." It was the first of two Summer Schools, planned within the project, in order to stimulate research cooperation between Europe and India in the project field, with emphasis on recent developments on environment-friendly biomass and biowaste conversion. The innovative elements of the specific activity can be summarized in the following:

- A multi-national audience, comprised of Indian, Italian, French and Greek students;
- A multi-national and multi-disciplinary teaching team, comprised of specialists for each topic;
- Strict student selection criteria targeting at, among other things, their multi-disciplinarity;
- A multi-level approach, where the socio-environmental aspects were in complete balance with more "traditional" techno-economic aspects;
- The presentation of a very wide range of the available and future biomass-to-bioenergy, biomass-to-biomaterial, and biomass-to-biochemicals chains, with emphasis on the more promising ones;
- Personalized projects aiming at the application of the summer school material on real life cases, deliberating in the meantime the creativeness of the attendants;
- The project topics covered the widest possible range of the relevant production and logistic chains.

The student projects in combination with the whole teaching approach provided the necessary tools for the students' future professional activities, contributing in particular to the process of building a common culture on the specific scientific and technological field.

Content Curation in Education

It is argued that Content Curation (CC) will be a critical strategic option for student-centered engineering and technology teaching in the 21st century (Antonio *et al.*, 2012). CC focuses on the extensive use of any kind of digital material, from whoever has access to the World Wide Web.

Using any kind of digital material is a common place in the current life style. Limiting our scope in the educational activities would further indicate the increasing tendency of saving, uploading on the web and transferring educational material through personal computers, corporate networks and portable devices. To put it bluntly, the conventional printed educational material shows rather insufficient in the digital age. Given that during our educational lifetime the digitalized educational material is almost everywhere, its efficient management, which will render it accessible and usable, is a real necessity. Nowadays, the primarily produced digital material has been being multiplied, whereas material already available in printed form has been being rapidly transformed into digital form (Yakel *et al.*, 2011).

The transition into a model of educational material which will be easily explorable, accessible and reusable is imperative, and it will replace the old, and inactive "dark" material, which offers limited accessibility. In the digitalized world of nowadays, which is also supported using of metadata, reusing any material is a common place. The potential of direct data and information "mining" accelerates the direct access of any student and trainee to material of digitalized format. From the point of view of a user/reader, the easiness of access to the digitally saved Material corresponds to the direct access to the knowledge. On the other hand, the owner/creator of the material is also protected, within the frame of existing technology, ensuring the control of the original creator's identity, as well as, possible corruptions of the original documents (Higgins, 2011).

Eco-Friendly Learning and Other Outcomes

"Green" Engineering Lessons

Throughout the ca. 10-year period of the application of this specific educational approach to the "Green" Engineering courses, more than 50 different student projects were assigned and presented. The distribution of the assigned molecules between the three major product market segments is shown in Fig. 1, whereas the structure of the teaching is shown in Fig. 2:

The surveyed student projects provided some insights both to the trends of modern, "greener" chemical engineering and to the prospects of the applied educational methodology (Seiderand and Widagdo, 2012). Some relevant findings from such a long class experience follow:

- There is a shift in the process technologies from "old school" heavily chemical catalytic processes to bio-catalysed, bioresource based "greener" ones;
- Relocation of production units takes place, especially when the commodities are concerned, from Europe and Western World to Asia. The low labour cost, coupled with a more flexible regulatory framework and environmental tolerance, create the "ideal" investment framework, favouring that part of the world. Quite often this happens without the incorporation of the lessons already learned in the Western World and at the expense of environmental and social sustainability;
- There is also a shift from process to product design due to the fact that the optimization efforts of the former have reached at its limits. Mostly the environmental targets set, in view of stricter regulations, are keeping the process optimization interest still active;
- Products related to quality of life objectives, i.e., food additives, nutritional supplements, and nutraceuticals, do gain an increasing importance in the overall world market. Most of the innovative products proposed by the student groups are somehow related with this product portfolio;
- Even the "hardcore" petrochemical products tend to focus on the research for raw material substitution in order to improve the environmental impact created from their production; i.e., butadiene;
- The product design is the kind of engineering work which can be carried out still in Western world, and not necessarily co-located with the actual production site;
- The proper use of the full set of the chemical engineering tools, requires the proper guidance and tutoring of the students throughout the whole duration of the engineering courses.

The analytic and synthetic skills which are developed step by step seem to be the major benefit of the educational process. Furthermore, the innovative thinking, which is the crucial element of product design, is cultivated during these courses, under the condition that the participating students succeed in overcoming their reluctance concerning "out of the box" creative thinking (Karaoglanoglou *et al.*, 2016).

The continuous improvement of the educational process depends also on measuring the student feedback for certain elements of each course cycle. This is achieved through the use of a tailored questionnaire at the end of each 3-course cycle. The so far

outcomes of this questionnaire are presented in [Table 1](#), where the students evaluated the course elements through marks from 1 (worst performance) to 5 (best performance):

“Green” Technology Management Lessons

A Decision-Making Tool: The outcomes of the simulation game, which takes place within the framework of the post-graduate biomass course - see [Box 1](#) - are discussed briefly in this section. The questionnaires which were collected provided data for the determination of the priorities of each interest group (see [Table 2](#)). Grouping the results can give a rough overview of the overall priorities of the region, which will affect the sustainability of a potential plant. The environmental impact of the plant, as well as its effect on the regional development (criteria 7 and 4) seem to play a decisive role according to the stakeholders, followed by the plant microeconomics and its socio-economic impact (criteria 2 and 6).

Further processing of these data can provide indications for the potential alliances and consensus platforms which can be built among several stakeholders and the possible friction points, which could jeopardize the sustainability of the future plants, as well. In particular, the affinity between each couple of interest groups can be assessed using an index which is generated by summing the absolute differences of their responses for all the decision criteria (see [Fig. 3](#)).

The lower this index is, the more easily an alliance between two interest groups can be built. Encouraging such alliances, using the available or new policy tools will be a crucial feasibility and sustainability issue for the implementation of the examined technology. As an outcome of [Fig. 3](#), it can be noticed that the couples of “biomass producers vs electricity distribution company”

Table 1 Student feedback to the educational methodology

Questions	Average score 2013	Average score 2014	Average score 2015
1. The interest of the courses?	4.2	4.1	4,0
2. The utility of the courses?	4.1	4.1	4,1
3. The interconnection of the 3 successive courses?	4.3	4.1	4,3
4. The educational methodology?	3.8	3.5	3,7
5. The course professors?	4.5	4.3	4,4
6. The invited course lecturers	4.0	4.0	4,4

and "bioenergy plant vs local government/authorities" present the largest differences. The relatively large index for the couple of bioenergy producer and local community also indicates that work is needed from the producer side in order to gain the confidence of the local community. Especially, the interaction of this couple should be considered as a key success factor for the whole chain. On the other hand, the low value of the index of the pairs of local community with local government, central government and the researchers (who were voted as the 8th stakeholder category by the students), shows that their common basis of understanding can either boost or block the investment.

A Web 2.0 Tool: The outcomes of the digital curation which took place on this course are very interesting and useful, too. In the Fig. 4a and b below, the impact of student scoops in the networked society can be seen. Despite the limited monitoring time for the students' posts in the curation platform, which was only one month, their impact can be considered as promising in terms of the number of both the views for their topics and the followers for their micro sites.

Summer School Toolbox: The initial scope of the SAHYOG Summer School (see above) was to provide the attendants with a overview of the state of the art of biomass related technologies, as well as to supply them with the necessary tools that will let them

Table 3 SAHYOG summer school (S3) evaluation (5 = very positive, 4 = positive, 3 = neutral, 2 = negative, 1 = very negative)

No.	Question	Ranking
1	SUBJECTIVELY: Achievement of your original expectations from S3?	3.8
2	OBJECTIVELY: Achievement of the S3 targets as defined by its organizers?	3.9
3	ON A HINDSIGHT: If you knew what S3 was really about, would you attend it now?	4.1
4	RECOMMENDATION: Would you now recommend S3 to an interested colleague?	4.4
5	COOPERATION: Would you be interested to join a future S3 as an organizer/lecturer?	4.3

assess the applicability of these technologies under different socio-environmental conditions, i.e., the ones in India and in Europe. The results of the course evaluation by the attendants can be seen in [Table 3](#).

During the Summer School the students were also assigned to prepare a short report describing a biomass project of their own interest. In order to do that, the students had to answer briefly 5 questions (A to E) asked by the teaching staff: (A) Biomass feedstock used – (B) Biomass conversion technology applied – (C) Biomass derived product(s) delivered at the end of the pipeline – (D) Location of the “ABC” application – (E) Potential of real-life development of the proposed ABC chain. Moreover, the student project proposals were reviewed by experts, members of the Workshop organizing committee, and the best ones were honoured with a success certificate presented during the closing ceremony of the Workshop.

Concluding Remark

The students who attended any of the above-mentioned dimensions of the educational activities coordinated by BTU were supplied with a toolbox which will be applicable in any future “green” process and product design, or more generally, complexity dealing challenge. During these activities the multiple dimensions of sustainability issues were analysed, beyond the traditional techno-economic feasibility, with an interdisciplinary approach. The students got familiarized with the methodological approaches which should be followed during the data collection and decision-making process, as well as with the productive use of the already available tools; i.e., software, GHG assessment, GIS, etc. In all cases, the students developed skills on how to deal with these complex problems in multidisciplinary way, by not becoming a top expert for every case but by contacting the right expert and through him/her exploiting sustainably the state of the art of science and technology.

Acknowledgements

The present overview of education and training activities by the BTU group of NTUA is based on several reports of individual BTU actions presented at various audiences, mostly as part of the Education Sessions of the National Chemical Engineering Conference Series (2013–2019). Other significant sources of relevant research findings include the Doctoral Theses of two of the co-authors of the present article.

Nuclear Electricity – Renewability, Losses and Recycling

Manojit Ghosh, Shashank Sharma, and Partha S Banerjee, Indian Institute of Engineering Science and Technology, Shibpur, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Nuclear reactions are known to have tremendous potential to generate an enormous amount of energy in the form of heat, light, sound etc. Sun being the best example for fusion nuclear reaction, it made clear that controlling the energy produced during fission reaction was practically impossible for the mankind. However, fission energy was viewed to be of human enterprise. The amount of energy produced during a nuclear reaction made it of quiet an importance in the human world. Electricity was first generated using the nuclear reactor on September 3, 1948, at X-10 Graphite reactor in Oak Ridge, Tennessee, United States ([Graphite Reactor](#)). Nuclear fission reactors brought the direct service of the vast majority of the nuclear energy to the humankind with the commencement of Obninsk Nuclear Power Plant in USSR on June 27, 1954 ([Russia's Nuclear Fuel Cycle](#)). Despite all the advantages the nuclear energy could have provided to the human world, its destructive use was first witnessed by mankind during World War II in Hiroshima and Nagasaki of Japan used by the United States of America.

Nuclear power generation has been a huge step in human civilisation. Having known the enormous potential of electricity generation by nuclear fuel, scrutiny instantly turned towards the risks involved during the process and its consequences. The dubiety of nuclear power to be classified as a permanent source of electricity replacing all other alternative source prevails regardless of its extensive prospective. The debate over the nuclear energy being renewable or non-renewable resource hasn't seen a clear side through various sets of belief. Power generation efficiency for nuclear power was found to be around 67%, as discussed in further sections, challenge nuclear powers capability of become the future of power generation. To add to scepticism over the prospect of nuclear power, the waste handling has played an important part. The nuclear waste handling has been one of the biggest road blocks for the development of nuclear power generation infrastructure. The highly radioactive wastes take centuries to get less harmful to the environment. The storage of such wastes for so long time leads to serious criticism of nuclear fuel. However, in modern days, with nuclear reprocessing gaining acceptance, even though its risks, the waste handling is expected to get efficient in next few decades. This article discusses how the nuclear power are getting closer to other alternative sources and claiming to replace them with a lesser risk involved.

Nuclear Energy – Renewable or Non-Renewable Resource?

The Library of Congress defines renewable energy as “a sustainable energy source that is replaced rapidly and indefinitely, by a natural ongoing process.” This creates a debate for the qualification of nuclear energy into a list of Renewable resources, which otherwise is a clean source of energy. The Library of Congress also notes that nuclear fuel sources are “not essentially renewable” since they are liable to be depleted. The U.S. Department of Energy classifies Uranium (U) as a non-renewable source. Experts still question whether the world should call nuclear power “renewable” ([Library of Congress BERA](#)). There are school of thoughts who want to classify nuclear energy as renewable cite the fact that it has low carbon emission, just the way renewable sources such as wind and solar do. Non-renewable fuels, such as natural gas and oil, produce byproducts that harm the environment through global warming emissions. Those opposed to calling nuclear power renewable note that nuclear power plants create harmful waste. According to the ones opposing the idea, if the goal to build a renewable energy infrastructure is to lower carbon emission then there is no reason for not including nuclear energy in that list ([Cohen, 1983](#)).

An interesting argument for including the nuclear energy in renewable source portfolio came from Bernard L Cohen, a former professor at the University of Pittsburg ([Cohen, 1983](#)), USA in the same article. Professor Bernard came up with an interesting definition of the word indefinite, which described the time span required for a source to become renewable in numbers by using an expected relationship between earth and sun. According to Professor Bernard, a source can be said to be renewable if its deposit could prove to last as long as the relationship between earth and the sun is expected to last, i.e., 5 billion years. Hence, according to his argument, the nuclear energy could be declared as renewable if U deposit inside the earth could last for the amount of time span which was indefinite by Professor Bernard's definition. According to the paper by Professor Bernard, using the breeder reactor makes it possible to fuel earth with nuclear energy indefinitely. It was claimed in his paper that although the current supply of U discovered has the capability to fuel earth for 1000 years, but there are still some U deposits available which are yet not extracted. It is mentioned by Professor Bernard in his paper that there are some other deposits of U from which the extraction process could be expensive though. Extraction from sea water and also the depletion of U from the earth crust by sea water has been acknowledged by Professor Bernard. All of those possible U resources if used in a breeder reactor would be enough to fuel the earth for another 5 billion years and hence renders nuclear energy as renewable energy ([Johnson, 2009](#)).

The arguments presented by Professor Bernard left a huge void for reasoning in the debate of renewable and non-renewable nature of nuclear energy. The biggest opposing argument relied on the fact that U deposits tend to end up soon. The claims of Professor Bernard for the indefinite supply of nuclear fuel didn't find an arc since the deposits still are expected to exhaust sooner than what was defined as indefinite. Another major argument was the polluting nature of the nuclear fuel. Although carbon

emission was found to be less in the case of nuclear fuels than the rest of non-renewable fuels, yet the amount of harmful wastes led to a solid argument against its case. Yucca Mountain is one of the examples used quite often to prove this point.

This confusion over the nature of nuclear fuel never could find a shore of settlement. A recent decisive statement by Helene Pelosi, the interim Director General of IRENA (International Renewable Energy Agency), saying IRENA's support won't be extended to nuclear energy program due to its waste production, long and complicated process and higher relative risk (Kanter). The statement proved that the decision over renewability of nuclear fuel has nothing to do with the sustainable supply of fuels. Such a decision has led to the supporters of nuclear energy to look for an efficient way to dispose of wastes before asking IRENA again to tag nuclear energy for a renewable source of energy along with a clean one.

Efficiency

The vastly expanding renewable energy sources like solar, wind, hydro and wave power to replace the current non-replenishing sources are resulting in significant challenges in balancing supply and demand in the smart grid (Lund *et al.*, 2012). Improving resource efficiency is an important factor which can lead to the answers to various challenges. Measurement of Primary Energy Factor (PEF), which describes the amount of energy from primary resources are being used for each delivered unit of energy, is most popularly known method for estimating resource efficiency (Eriksson, 2017). Improvement of energy efficiency on large scale is required, as addressed in e.g., European energy targets (European Commission, 2014), where efficiency measures are targeted to resources which are vast over just electricity.

Primary Energy factor has various flaws in itself. A simple stating of primary energy factor can be a relationship between the total energy input and the final energy used (Russia's Nuclear Fuel Cycle). The aim of PEF to focus on the efficiency relationship of the resource leaving aside its environmental impacts and mankind risks, accounts for a questionable flaw of it. However, its accurate study could serve the purpose of understanding the efficiency of a resource.

Nuclear Power Plant Efficiency

Nuclear energy, famous as one of the clean sources of energy, less is popular about its very low efficiency. At an average, the yield of a nuclear power plant is approximately 30%. In other words, this means 30% of the energy generated by U fission ends up being converted into electricity. The rest is lost or used up during the different steps of the transformation process of potential energy.

In a discussion of Modahl *et al.* (2013), a comparison of primary energy content for hydro, nuclear and wind power is mentioned. The discussion is presented for nuclear energy by two different approaches. In the first approach, power energy is referred as the energy stored in the turbine of the power plant. Here the life cycle efficiency assessment gives nuclear energy to be 33% efficient (International Energy Agency IEA, 2004). In the other approach, the primary energy is defined as "the energy content of the fissile isotope in the natural U extracted from the mines" (Frischknecht *et al.*, 2007). This approach was more realistic, covering the whole life cycle back to the cradle. However, not much of difference was seen from the data obtained in the first approach.

A specific set of directives responsibly appeal to the European standards with a recommendation of PEFs for alternative sources to electricity generation to be established. In Global Emission Model for Integrated Systems (GEMIS), a model and a database both are hosted by IINAS for the life cycle assessment and material flow analysis model, which is used in EU and OCED (Organisation for Economic Co-operation and Development) countries. Table 1 shows a very productive compilation of PEF for nuclear energy from sources which are either taken from GEMIS model or have been found to be consistent with the model.

The fission of one gram of U235 releases approximately 24 MWh or 1 MW day (MWd) of thermal energy. This fact makes it easy to use the concept of combustion rate, also known as "burn-up", which is expressed in MWdays per tonne of heavy metal

Table 1 Compilation of primary energy factors for nuclear power from various sources

<i>Method/Data</i>	<i>Primary energy factor</i>	<i>Degree of efficiency (%)</i>
IEA (2004)	3.0	33
Ecolnvent	3.19–3.58	27.9–31.3
IEA (2009)	3.4975	28.59

Nuclear – FR	4.05	24.7
Nuclear – UK	3.15	31.7
Nuclear – SE	2.92	34.2
Partial Substitution	2.5	40
Physical Energy content	3	33
EN 15603: 2008	2.8	35.7

Note: Eriksson, O., 2017. Nuclear power and resource efficiency – A proposal for a revised primary energy factor. Sustainability 9, 1063.

Fig. 1 Life-cycle chain of energy products. Reproduced from Eriksson, O., 2017. Nuclear power and resource efficiency – A proposal for a revised primary energy factor. Sustainability 9, 1063.

Table 2 Calculated PEF for nuclear power (Energy Density = 23.564 GWh/kg)

Scenario	Burn up (GWd/ton)	Power to heat ratio	PEF
Baseline	50	33	60
Conservative baseline	40	27.9	88
Progressive baseline	73	41	32

(The trend and the Benefits of Multi-Energy Services for a New Generation of Industrial and Commercial Customers) (MWd/tHM). The total thermal energy released by nuclear fuel is proportional to the burn-up it reaches at the end of its reactor life (National Strategies for Management of Fluctuations in Wind Power and CHP). The thermal efficiency of a nuclear power station is the efficiency of the thermodynamic cycle by which the heat generated by the fuel is converted into steam through steam generators. The thermal efficiency of a conventional nuclear power station is around 33%–36% agreed through peer review between EUR-ELECTRIC and VGB experts (Efficiency in Electricity Generation, 2003).

In the definition of primary energy, it is vital to consider all pre-combustion losses. In Fig. 1, different types of losses are graphically illustrated.

The prevailing $PEF = 3$ for nuclear power sets the relation between W and the sum of $W + X$. In addition, some data sets considered the contributions of pre-combustion operations shown as A1 and A2, along with the infrastructure losses B1 and B2. Nevertheless, their contributions were found to be minor. Obvious observation shows that losses from the fuel have been neglected in the calculation of prevailing PEF. However, one of the most problematic issues with nuclear power is the problem with radioactive waste. The waste is partly low or medium active (used equipment, clothes, etc.) while the majority of the high active waste is spent fuel. Radioactivity is a form of energy, meaning that radioactive waste contain enormous potential primary energy. This loss is not accounted for in the PEF, which suggests that the energy in spent fuel should be seen as a potential resource that has not been consumed. This means that the current PEF for nuclear power is inconsistent with most current plans for the final disposal of spent fuel. It should also be noted that this circumstance separates nuclear power from the combustion of solid (like coal or biomass) or liquid (e.g., oil, gasoline) fuels, where fuel-related energy losses are moderate due to more or less complete combustion processes.

In the calculations made by Eriksson (2017), PEF values are measured. The reported PEF values demonstrated that the losses which are being considered while considering $PEF = 3$ are very high. In the paper, energy density, burn up value and heat to power ratio led to values which could be used to conclude that “the current values underestimate the poor use of U”. For the calculations

$$PEF = \frac{ED \left(\frac{GWh}{kg} \right) \times 1000 \left(\frac{kg}{ton} \right)}{BU \left(\frac{GWd}{ton} \right) \times 24 \left(\frac{h}{d} \right) \times \eta}$$

Where ED=Energy density, BU=Burn up value and η = heat to power ratio.

Resulting PEFs for the different assumptions on burn-up and power-to-heat ratio are displayed in Table 2 (Eriksson, 2017).

Table 3 Transmission and Distribution losses in various countries

Country	% Losses in 2000	Country	% Losses in 2000
Finland	3.7	Sweden	9.1
Netherlands	4.2	Australia	9.1
Belgium	4.8	U.K.	9.4
Germany	5.1	Portugal	9.4
Italy	7.0	Norway	9.8
Denmark	7.1	Ireland	9.9
USA	7.1	Canada	9.9
Switzerland	7.4	Botswana	10.0
France	7.8	Spain	10.6
Austria	7.8	New Zealand	11.5
Trinidad and Tobago	7.9	Jamaica (2003)	18.8

The table suggests the value of PEF varies with the different reactor scenario. The variation is highly sensitive to actual burn up and may vary between 32 and 88 or more. This implies that PEFs for nuclear power has to be calculated on an individual plant level instead of using the current generic value. So, with 33% efficiency already being too low, it can be said that it still underestimates the amount of wastage of fuel.

Transmission and Distribution Losses

In the previous section, it is already seen that nuclear energy losses are enormous. The conversion of radioactive energy to electrical energy is highly inefficient. In earlier sections, it is illustrated that almost 67% of energy is theoretically already being lost during the generation of electricity from nuclear fuel. To add to this, transmission and distribution losses are a challenge within themselves as well. In India, average Transmission and Distribution losses, have officially been indicated to be 28% of the total energy generated (Singh and Kumar, 2014). India is found to be the country having the highest T&D losses, with almost 30%–50% of the losses coming from eastern India (State Electricity).

The transmission and distribution losses associated with the process of supply of electricity are classified as technical and non-technical losses (Concept notes on T & D losses). The technical losses are almost inevitable, as they arise due to energy dissipated in the electrical system equipment used for transmission, transformation, sub-transmission and distribution of power. The losses can be further sub-grouped depending upon the stage of power transformation & transmission system as Transmission Losses (400kV/220kV/132kV/66kV), as Sub Transmission Losses (33kV/11kV) and Distribution Losses (11kV/0.4kV). Technical Losses generally vary with the square of the load current being distributed. As a result, losses will increase as more capacity is used. Losses are also proportional to the length of the line. These losses consist of both variable and fixed components. Fixed losses comprise of system configuration, the pattern of loading of transmission and distribution lines, magnitude and types of loads, characteristics of equipment etc. While the variable losses arise due to weak and inadequate sub-transmission and distribution lines, inadequate sizing of the conductors used, lengthy transmission and distribution lines and inadequate reactive compensation in the system.

The non-technical losses or commercial losses are a component of distribution system losses that are not related to the physical characteristics and functions of the electrical system. These losses arise due to defective meter, error in meter reading, customer frauds, illegal connections, etc.

In India, transmission and distribution losses have raised from 15% in 1966–67 to 34.33% in 2003–04. However, at present these losses are about 27%. The technical losses in the lost 27% consist around 15% and rest of the 12% are constituted of commercial losses Modahl *et al.* (2013). While comparing this loss with the losses in other countries given in Table 3, it indicates that the losses in other developing countries are around 10% less than India. With India producing around 35 TWh of nuclear energy, it requires the country to build smart grid which can contribute to the infrastructure of nuclear power plants and reduce losses to a minimum amount by avoiding the commercial losses.

In Table 3 (Electric Power in Asia and Pacific, 1997), transmission and distribution losses of various countries are listed in the increasing order during the year 2000.

Nuclear Wastes

Nuclear wastes are the left over materials that nuclear fuels become after being used in the nuclear reactor. Physically nuclear wastes look exactly the same as the loaded fuel – assemblies of metal rods enclosing fuel pellets. Waste materials are generated due to continuous operation of a nuclear reactor or during decommissioning of it. Compared to other power plants, the amount of wastes produced in nuclear power plants are very low (Efremenkov, 1989). It is needless to mention that these waste materials are highly radioactive in nature. Decommissioning of the nuclear power plant is a common practice normally after 20 years of its usage. Nearly 3 power plants in Germany along with a few in France have already been decommissioned (VGB Brochure). During the decommissioning of a nuclear plant, the waste generated can be recycled to give lesser radioactive and constructive products.

Table 4 Heavy metal composition of 4.2% enriched nuclear fuel before and after running for 3 years ([What's about the wastes](#))

<i>Components</i>	<i>Charge</i>	<i>Discharge</i>
Uranium	100%	93.4%
Enrichment	4.2%	0.71%
Plutonium	0.0%	1.27%
Minor actinides	0.0%	0.14%
Fissionable products	0.0%	5.15%

However, there are certain wastes which couldn't be recycled and are to be regarded as radioactive wastes. These wastes are to be properly disposed of, along with the other radioactive products from a nuclear reactor.

The radioactive wastes can be classified by international standards based on the quantum of radioactive nature into Low – level radioactive, Intermediate – level radioactive or High – Level radioactive. Low and Intermediate level radioactive wastes are produced by the contamination of various materials by the radionuclides which are formed as a result of fission in the reactor or released from the reactor walls. Usually, the radionuclides are collected in the reactor coolant system and, to a lower extent, in the fuel storage pool. Low-level radioactive wastes are less on radiations but very high in volume as compared to intermediate and high-level radioactive wastes. Hence, reduction of the volume of low – level radioactive waste is an important measure to reduce the interim disposal costs.

The most important and hazardous waste being produced comprises of components being removed from the reactor during refueling or maintenance or operational wastes such as radioactive liquids, filters, and ion-exchange resins which are contaminated with radionuclides from circuits containing liquid coolant. The chemical composition of a typical US nuclear reactor's waste is given in [Table 4](#).

Liquid Wastes

The wastes streams arising in nuclear reactors can vary depending upon the various reactors operating all over the world. These streams can vary in both in terms of activity and concentration. A reactor whose core is water cooled, produces more wastes than a gas cooled one. Liquid concentrates at Heavy Water Reactors (HWR) is virtually absent due to its clean up system working with ion exchange technique. Moreover, Boiling Water Reactors (BWR) produces more liquid wastes than Pressurized Water Reactor (PWR). Some active liquid wastes are also generated during the clean-up of BWR and PWR and Decontamination of the reactor core ([Efremenkova, 1989](#)).

Wet Solid Wastes

Waste Solids are another major category of produced wastes in nuclear reactors. The principle PWR waste flows include ion exchange resins (bead resins), filter cartridge inserts, metal components, evaporator concentrates, oils, filter concentrates, etc ([Efremenkova, 1989](#)). Spent resins are the most significant part of produced solid wastes. Bead resins are mainly used in the systems such as coolant purification, fuel pool cleaning and coolant preparation. They are mostly seen in deep demineralisers. BWR's have a considerable amount of powdered resins for which a significant source is "condensate polisher" used for further cleaning of water condensed after evaporation from the surface. Filter wastes are produced by the interaction of pre-coated filters with liquid wastes which gives wet solid wastes popularly known as filter sludges. The subsequent drying of the filter concentrates allows interim storage as solids in waste containers.

Gaseous Wastes and Aerosols

Air borne radioactive wastes of either particulate or aerosol type can be generated in a reactor which is gas cooled. The particle size can be of wide range in either solid or liquid form depending on the type of reactor in particulate wastes. These wastes could be a well-formed combination of various components both radioactive and non-radioactive in nature. Three major sources of aerosols are generated by the emission of activated corrosion products and fission products, radioactive decay of gases to in-volatile elements; and adsorption of volatile radionuclides formed in the fission process on existing suspended material ([Efremenkova, 1989](#)). Volatile radionuclides which form radioactive gaseous wastes are halogens, noble gases, tritium, and carbon – 14. These gaseous wastes are of immediate effect to the environment. Hence they are to be treated before releasing to the atmosphere to remove radioactive constituents from the effluents.

Decommissioning and Dismantling of Nuclear Power Plants

An important problem of nuclear energy is that unlike other industrial facilities, nuclear power plants have to be decommissioned at the end of their technical and financial life span leading to its dismantling. These dismantled nuclear reactors are the largest contributors for radioactive wastes. Before dismantling of a nuclear reactor, the plant is converted to a "safe enclosure" for a limited period, where the main radioactive component of the plant is made free from fuel assemblies and other radioactive components. This is left in sealed state until decommissioning. A large number of successfully implemented technologies are available

(Efremenkov, 1989) for dismantling itself, both for decontamination and disassembly and for the disposal of the materials accumulating. In Germany, 19 nuclear power plants and prototype plants of the first construction generation, mainly those with a small and moderate output, had already been dismantled by the end of 2010 (VGB Brochure). In the United States as of 2011, there are 13 plants which are shut down and are in some phase of decommissioning (Sovacool, 2011).

In dismantling of the nuclear section, conventional recycling followed by removal of any surface contamination can be done. With reference to the total mass of nuclear section only 2% is to be transported to the repository as radioactive wastes. Since the waste accumulating during decommissioning of the nuclear power plants are similar to the radioactive waste arising during nuclear power plant operation, the same conditioning methods are used during their treatment.

However efficient it may seem, given the amount of decommissioning of a nuclear plant, challenges for it is very high. "The Yankee Nuclear Power Station in Rowe, Massachusetts, took 15 years to decommission or five times longer than was needed to build it. And decommissioning the plant – Constructed early in the 1960s for \$39 million to cost \$608 million" (Drollette, 2014). For this reason, proper decommissioning and dismantling of nuclear plants are either compromised or delayed which serves to increase of hazard for the environment.

Nuclear Safety Regulations

European Union (EU) is one of the most dependent consumers of nuclear power plants. With 128 nuclear power plants (119 GWe) operating in 14 of the all 28 EU member states has contributed for almost 25% of the total consumption of electricity in the whole of EU (Nuclear Power in European Union, 2018). Major production of nuclear energy takes place in France. These nuclear reactors, although are set up under the legislation of specific countries, but the electricity is distributed throughout the EU. Major concern involved with nuclear energy is the risk relating safety and waste management. A legal framework was set up under The European Atomic Energy Community (EURATOM) set up in 1957, within a treaty named EURATOM treaty which is applicable for all EU members. However, initially, the treaty had an intention for peaceful usage of atomic energy in Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands.

EC deals with 3 major aspects of the nuclear activities:

- Safe operation, radiation protection and radioactive waste management of nuclear installations.
- Nuclear safeguard with a view to ensure the use of nuclear fuels strictly for the constructive user-defined purposes.
- Nuclear security protection by physical protection of nuclear fuel and checking of intentional malicious acts.

A EC nuclear safety directive was released in 2009 with an emphasis on the national liability of ensuring nuclear safety. An amendment in the directive in the year 2014 to ensure high-level nuclear safety by reducing the risks and consequences of nuclear accidents and addressing the safety objective for the entire installation cycle was introduced. The EU prescribed a less controversial set of directives for radioactive wastes and spent fuel management in 2011 (Council Directive 2011/70/Euratom). The salient features indicated for proper legislature throughout the EU through the means of the directives are listed below:

- Establishment of uniform safety standards to protect the health of workers and the general public from ionizing radiations.
- EU countries should have national policies to safeguard the public health and reduce radioactive waste related risks.
- Proper disposal of spent fuel and management of radioactive waste needed to be ensured inside the country by the proper framework and implementation of national programmes in EU countries by providing adequate funds.
- An inventory of future estimates to be prepared with an appropriate discussion about decommissioning, classification and management of spent fuel.
- A proper self-assessment and international peer assessment to be coordinated by EU countries for the national framework of nuclear waste disposal as frequent as every 10 years if not more.
- Transparency to be maintained by the issue of public information for proper knowledge of public in EU countries.
- Export of radioactive wastes for disposal outside EU nations to be allowed only under strict conditions.

Nuclear Waste Management

Effective management of radioactive wastes involves segregation, characterization, handling, treatment, conditioning, and monitoring prior to the final disposal. In Fig. 2, a flow chart depicts the radioactive waste management method being employed in the nuclear commerce.

A radioactive spent fuel constitutes of a mixture which composed of short-lived radioactive wastes and long-lived wastes. The radioactivity of short-lived waste is considerably very small after some time of storage in the deep geological depository (repository). The wastes are treated to reduce its volume to the minimum before permanent storage. The reduction in the volume can be done either by incineration and compaction of the wastes. While incineration of the wastes is performed, the non-radioactive substances like plastics, fabrics, wood, etc. are removed from the wastes. Some of the radioactive components also get transferred into ash, shoot,

Fig. 2 Management of radioactive wastes.

smoke, etc. generated during the process. These components can again be separated and taken to the compressing unit. During high-pressure compaction, the waste is reduced in volume so that it occupies less space in the repository in which it is stored.

High-level nuclear wastes are generally those wastes that are generated towards the core of the nuclear reactor. These wastes are constituted of certain radioactive isotopes which can be expected to have extremely long half-lives (some even 100,000 years) ([Radioactive Waste Management: Indian scenario](#)). The management of such waste is a three-fold process in the scenario of a country like India. The major steps towards the disposal of high-level nuclear wastes are:

- Immobilisation of high-level liquid waste into vitrified borosilicate glasses.
- Engineered interim storage of the vitrified waste for passive cooling & surveillance over a period of time, qualifying it for ultimate disposal.
- Ultimate storage/disposal of the vitrified waste in a deep geological repository.

Internationally, high-level wastes and heat generating wastes are disposed separately from low-level wastes with negligible heat generation capacity. High-level wastes are suitable to be stored in repositories with salt formation capability which enables heat dissipation easily. Various technical and natural barriers inside the earth surface do not allow the harmful radioactive radiations to return back to the biosphere, hence protecting humans from its exposure.

Nuclear Fuel Cycle

Nuclear fuel cycle, or nuclear fuel chain, is the complete progression of radioactive nuclear fuel in order to extract energy, through a series of different stages. Fuel cycles can have a variety of configurations, depends on various economy, natural resource availability, energy growth projection, and politics. The various configurations are varied by variations in steps in the front end, service period and back end. The front end consists of steps for the preparation of fuel; service period consists of steps in which fuel is being used in the reactor; and back-end consisting reprocessing or disposing of spent fuel.

Nuclear Recycling

A characteristic feature of nuclear energy is the capability to extract energy from the used fuel through a series of recycling processes. In the previous sections, it was seen that the PEF value of nuclear energy was 3 giving a very poor efficiency of 33% for the U fuel ([International Energy Agency IEA, 2004](#)). This indicates that a lot of radioactive energy is contained inside the left over part of the fuel that comes out as wastes from the reactor. This energy can be extracted from the fuel if the concentration of U-235 can be increased to a level where the waste can be again used as a fuel in the reactor. So, nuclear reprocessing is a series of chemical operations that separates Pu and U in the nuclear wastes contained in the spent fuel from the reactor ([Nuclear Reprocessing](#)).

Once Through the Nuclear Fuel Cycle

The simplest and most common form of fuel cycle is the once through the nuclear fuel cycle. This type of cycle finds its popularity due to its economic benefits. U is mined from its ore, enriched to a higher concentration, used as a nuclear fuel in the reactor and then is obtained as a nuclear waste which is stored in a repository until it is no longer dangerously radioactive. The problem with such a cycle is that the decay of radioactivity from the nuclear waste would take thousands of years to disappear. Storage of such radioactive substance for such long duration of time adds to the limitations to such a fuel cycle. Further, U is not abundant in the earth's crust and this kind of a cycle can cause a serious scarcity of U in near future. Fig. 3 shows a typical once through nuclear fuel cycle.

Closed Fuel Cycle

Closed nuclear fuel cycle includes recycling of the nuclear fuel (Fig. 4). As have seen noticed, the nuclear wastes mainly consist of U-238 isotopes along with Plutonium (Pu) and other materials. So, more energy can be obtained from the nuclear wastes if it is properly dealt with. The function of the recycling plant is to separate the radioactive U from the other less radioactive materials. U which could be further used and separated and is concentrated to use again. While the remaining part of the nuclear waste is the one which has been used for the fission reaction. This part is comparatively less radioactive and can reach to a lower radioactivity zone in nearly 300–500 years (Touran, 2009), which is far less than the general radioactive waste.

Fig. 4 Closed nuclear fuel cycle. Reproduced from Touran, N., 2009. Recycling Nuclear Waste and Breeder Reactors, © Whatisnuclear.com 2007–2018.

Fig. 5 Breeder nuclear fuel cycle. Reproduced from Touran, N., 2009. Recycling Nuclear Waste and Breeder Reactors, © Whatisnuclear.com 2007–2018.

Breeder Fuel Cycle

Breeder reactors consist of a number of free neutrons which converts the spent fuel content of U-238 into Pu-239 giving more fissile materials. Breeder reactors are fast reactors since the neutrons present in these reactors are very fast moving. Moreover, breeder reactors are nuclear reactors of highest efficiency as very high amount of nuclear fuel is being used inside the reactor and giving a very low amount of radioactive waste. Fig. 5 is a typical example for a Breeder nuclear fuel cycle.

Fig. 6 A Self-explanatory flow chart for PUREX processing (Processing of Used Nuclear Fuel, World Nuclear Association).

Reprocessing of Spent Nuclear Fuels

Reprocessing used fuel to recover U and Pu avoids the wastage of a valuable resource. Earlier, reprocessing of nuclear fuel was done for weapons purposes only. This is the reason for reprocessing being politically controversial for its potential to contribute to nuclear proliferation and potential vulnerability to nuclear terrorism.

Processing used fuel is similar to the processing of concentrate of any metal mineral to recover valuable metals present in it. Instead of an ore, the mineral to process while reprocessing of spent fuel is the hard ceramic uranium oxide. The ore also has a substantial amount of other fission products and actinides for the reactor. The separation techniques can be widely classified into water and organic solvent techniques, electrochemical techniques, pyro-processing, electrolytic separation, and, radio-analytical separation.

An important and commercially most popular reprocessing technique employed for recovery of nuclear fuel by reprocessing of spent fuel is PUREX, which efficiently comes under the category of water and organic solvent technique. All commercial reprocessing plants use the well-proven hydrometallurgical PUREX process, which separates U and Pu very effectively. In the next section, this process is discussed in a better depth.

PUREX

PUREX stands for Plutonium Uranium Redox Extraction ([Choppin et al., 2001](#)). Actually, PUREX is a standard aqueous nuclear reprocessing method to recover Uranium and Plutonium from spent fuel. It is based on liquid-liquid extraction ion-exchange ([Paiva and Malik, 2004](#)). In the primary step, dissolving of spent fuel in nitric acid at a concentration of 7M takes place. Chemical separation of U and Pu is then undertaken by solvent extraction steps. The solid particulates are removed through filtration process. In case of an emulsion formation, the solid is given the reference as a third phase. The organic solvent used includes 30% tributyl phosphate (TBP) in a hydrocarbon. The extraction of Uranium and Plutonium ions take place as a similar complex represented by $\text{UO}_2(\text{NO}_3)_2 \cdot 2\text{TBP}$ ([Burns, 1983](#)). Separation of Plutonium from Uranium is done by treating the hydrocarbon solution with reducing agent like ferrous sulfamate, N,N-diethyl-hydroxylamine and hydrazine which converts Pu to Pu^{+3} that passes into aqueous phase. The leftover U is removed from the solution by back-extraction into HNO_3 of concentration of 0.2M ([Greenwood and Earnshaw, 1997](#)).

This process recovers 99.5% of the U and Pu in the spent fuel rod assembly ([IAEA, 2008](#)). The Pu obtained by recovery using PUREX is weapon grade Pu – 240, which is very favorable for use in nuclear weapons. However, PUREX is the most effective method for nuclear reprocessing amongst all other methods. Although the production of a separated pure Plutonium stream remains as a drawback for this process. This drawback encouraged the modification of PUREX process and indicated the virtues of modified processes like UREX. The above portrayal of PUREX operation can be observed in detail in [Fig. 6](#).

There are a number of modifications in the PUREX processing method. Some of the famous processes that are popular in various parts of the world are UREX, TRUEX, DIAMEX, SANEX, etc ([Nuclear Reprocessing](#)). There are some other obsolete methods unpopular due to the quality of reprocessed fuel. Some of the obsolete methods not prevailing in modern industries are Bismuth Phosphate, Hexone or Redox, Pyro-processing, voloxidation, etc. However, the discussion of these methods shall be beyond the attraction of this article.

Summary

- Nuclear energy has tremendous potential for generation of electricity. This potential is utilized in nuclear power plants where inside a reactor the nuclear energy, in the form of heat, is obtained which run the turbine to generate electricity.
- Sustainable nature of nuclear energy has been an argumentative topic. Selecting a side to the debate is a very difficult task given the renewability and replenishment issues of nuclear energy.
- Prevailing PEF value for nuclear power generation is 3. PEF is a measure of resource efficiency of energy sources. However, this value of PEF underestimates the poor efficiency for U fuel in a nuclear power plant.
- Nuclear production losses are found to be very high. Nearly 67% of the nuclear energy is lost during nuclear power generation. Adding to these losses, a further 28% of the produced electricity in a country like India is lost as transmission and distribution losses.
- Nuclear wastes are radioactive substances that are produced either as a result of the operation or decommissioning and dismantling of the nuclear power plant. These wastes comprise majorly of liquid wastes, wet solid wastes and gaseous wastes or aerosols.
- EU directives focus on the establishment of nuclear safety and radioactive waste management.
- Effective management of radioactive wastes involves segregation, characterization, handling, treatment, conditioning and monitoring prior to final disposal.

- Nuclear recycling is a characteristic feature of nuclear energy. A lot of energy gets lost unused from the nuclear fuel which gets removed as nuclear waste. However, transforming U – 238 into radioactive Pu to reuse it as nuclear fuel is done by nuclear reprocessing. This is termed as nuclear recycling process.
- The most popular nuclear reprocessing method is PUREX due to its high recovery. However, production of separate stream of Pu still remains a challenge in the process indicating the virtues of UREX.

Introduction

In solar power tower plants, the central receiver system is the heat exchanger wherein the concentrated sunlight is absorbed and converted into useful thermal energy in thermodynamic cycles. Because the concentrated heat flux and the resulting temperature are substantially higher than in parabolic trough based system, high-performance materials are needed. A mirror field is used for concentrating the beam solar radiation onto a heat collection element viz. an absorber, which is cooled by a heat transfer fluid like, air, water or liquid metal. Just as cost reduction is the priority for further development in the solar collector field, in solar receivers, the priorities are thermal efficiency and durability. Typical absorber operating temperatures range between 500°C and 1200°C , whereas the concentrated flux covers a wide range between 300 kW/m^2 and 1000 kW/m^2 . Such a high flux concentration is challenging for the design and sustained operation of the central solar receiver based systems.

According to the geometrical configuration, there are basically two design options, external and cavity-type receivers. These can also be directly or indirectly irradiated, depending on the absorber materials used to transfer the energy to the working fluid (Becker and Vant-Hull, 1991). Directly irradiated receivers make use of darkened fluids or particle streams able to efficiently absorb the concentrated flux. The key design element in indirectly heated receivers is the radiative-convective heat exchange surface. Two heat transfer options are typically employed: Tubular panels and volumetric surfaces. In tubular panels, a coolant flows inside the tube and removes the heat collected by the external black panel surfaces by forced convection. It thus operates as a recuperative heat exchanger. Since heat transfer is through the tube surface, the maximum operating peak flux is around 600 kW/m^2 (Romero et al., 2016). In volumetric receivers, highly porous structures operating as convective heat exchangers absorb the concentrated solar radiation. The heat transfer medium (mostly air) flows through the porous structure and is heated by forced convection.

The design of volumetric receivers is one of conjugate heat transfer processes and interconnected optical and thermal requirements where trade-offs are unavoidable. Target operating conditions for their widespread industrial deployment are demanding (Mehos et al., 2016): Working fluid temperatures at receiver exit in excess of 1000 K , thermal conversion efficiencies over 90%, minimum service life of 10,000 cycles and overall costs below 150 USD per kilowatt of thermal power delivered. Operating temperatures play a conflicting role in their performance because thermal losses become significant at the very high levels required for efficient downstream thermochemical or power cycles.

Volumetric absorbers are usually made of thin heat-resistant metal wires (in knitted or layered grids) or either metal or ceramic open-cell matrix structures such, as monolithic honeycombs or reticulated foams. They are generally highly porous, allowing incident radiation to penetrate deep into the structure. Thin substructures (wires, walls, or struts) ensure good convective heat

transfer. A good volumetric absorber produces the so-called volumetric effect, which means that the irradiated side of the absorber is at a lower temperature than the medium leaving the absorber (Boehmer *et al.*, 1991). This minimizes thermal re-radiation loss from the absorber aperture.

There exists, however, scarce experimental evidence of solar receivers achieving a significant volumetric effect. The exception is a double-layer selective receiver composed of an external silica square-channel monolithic honeycomb and an internal layer of silicon carbide particles (Menigault *et al.*, 1991). A similar double-layer configuration where the internal particle layer was replaced by a ceramic silicon carbide monolith concluded otherwise (Pitz-Paal *et al.*, 1992). Comprehensive reviews on solar receivers investigated since the 1980s have been given by Romero *et al.* (2002), Ávila-Marín (2011), and Ho (2017). A detailed one-dimensional analysis has been recently employed to argue that receiver geometry and materials still lack adequate optimization for maximum thermal conversion efficiencies (Kribus *et al.*, 2014).

The current state-of-the-art for OVARs at the pre-commercial industrial scale was achieved by the HiTRec-SolAir receiver configuration (Hoffschmidt *et al.*, 2001). A stainless steel support structure on the back of a set of ceramic absorber modules forms the base of the receiver. Similar to ceramic burner tubes, the absorber modules are separated from the back and allowed to expand both axially and radially during start-up or shutdown. The absorber modules are spaced to avoid contact between adjacent modules. The support structure is a double-sheet membrane, which may be cooled by either ambient or recirculating air. Tubes attached to the absorber cups pass through holes in the front sheet and are welded to the rear sheet. The cooling air circulates between the two sheets and, as it leaves through the sides of the segments, also cools the support structure. The air reaches the absorber aperture through the spaces between the segments. Outgoing air and ambient air are mixed and sucked back into the segments. As they penetrate into the absorber structure, air is heated up by convection. On leaving the absorber structure, the hot air is ducted to the bottom of the cup. There an orifice adjusts the air mass flow rate to compensate the expected solar flux profile over the aperture so as to generate homogeneous outlet air temperatures from the cups. Finally, airflows through the cups, across the holes in the rear sheet of the membrane, and into the downstream power block.

The key advancement of this configuration with respect to previous solar receivers was the introduction of modular ceramic absorbers. This prevented fractures caused by the strong thermal shocks developing over larger absorbers during start up and shut down, whilst allowing for the achievement of higher operating temperatures. Modularity also facilitated cooling of the solar receiver, by means of recirculating air flowing through lateral gaps between adjacent absorber modules. The first HiTRec OVAR reached a maximum average outlet temperature of 980°C with a thermal efficiency of 68% (Hoffschmidt *et al.*, 1999). The next milestone in the development of this type of receiver was the qualification of the 200 kW HiTRec-II receiver. During the course of the test program, the HiTRec-II receiver was operated over a period of 38 days, accumulating a total of 155 operating hours with a thermal efficiency of up to 76% at 700°C (Hoffschmidt *et al.*, 2003). Subsequent developments of this concept led to the SolAir 200 kW receiver, as an intermediate step in the scaling up to the experimental demonstration of a 3 MW OVAR (Téllez, 2003). The SolAir-200 was able to achieve thermal conversion efficiencies of 83% at air outlet temperatures of 700°C (and remains the highest efficiency OVAR tested under fully realistic on-sun conditions).

Eventually, the SolAir 3 MW prototype was developed, installed, and tested at the Plataforma Solar de Almería, connected to a steam generator and a thermocline for heat storage (Téllez *et al.*, 2004). The receiver was composed of 270 ceramic absorber modules and had a total aperture surface of 5.67 m². The honeycomb absorbers were made of recrystallized SiC, with square flow channels and a normal open porosity of 49.5%. During testing, the average incident solar radiation on the ceramic volumetric absorber was 500 kW/m². The SolAir 3 MW receiver system achieved a thermal efficiency of 72% at air outlet temperatures of 750°C, and of 74% at air outlet temperatures of 700°C. Efficiencies were estimated at over 85% (and up to 89%) for air outlet temperatures in the range of 590–630°C and mean incident solar fluxes of 310–370 kW/m².

Although operational flexibility and initial results were satisfactory, it is obvious that open volumetric receiver thermal efficiencies must be still improved to around 90% in order to achieve cost-effective plant designs able to replace tubular receivers. In addition, long-term endurance tests must be conducted, radiation losses must be further reduced, and the radial distribution of recirculating air in operation could be further optimized (Marcos *et al.*, 2004). The thermo-mechanical properties, including corrosion, of the SiC ceramic employed in the SolAir-200 solar receiver were investigated by Agrafiotis *et al.* (2007), who conducted extensive experimentation on both irradiated and non-irradiated samples. The use of siliconized SiC was recommended due to its superior mechanical strength, allowable operating temperatures, and corrosion resistance.

The effects of high temperature cycling on the SiC thermo-radiative properties was researched by Rodríguez-Sánchez *et al.* (2016), who found that absorptivity generally decreased with prolonged cyclical exposures to concentrated solar radiation. Several CFD numerical studies were later conducted both to further explain the aerothermal behavior of the HiTRec-SolAir family of receivers, and to identify ways of increasing their thermal efficiency. Research has focused on the uniformity of air outlet temperatures downstream of absorber modules (Palero *et al.*, 2008); modifications of the honeycomb structure to increase the uniformity of air outlet temperatures and, thus, thermal efficiencies (Fend *et al.*, 2013); the influence of wind velocity and direction on the air recirculation system and air outlet temperatures (Roldán *et al.*, 2016); and the effects of receiver tilt angle, channel aperture size and air inlet speed of volumetric effect and thermal efficiency (Cagnoli *et al.*, 2017). The last study was conducted at the single flow channel level and showed that a trade-off exists between operation under volumetric effect conditions and achieving high thermal efficiencies.

Two recent studies have proposed geometric modifications to the HiTRec-SolAir receiver concept with the objective of increasing overall thermal conversion efficiencies. The first one consists of substituting the ceramic absorber with a cellular metallic

honeycomb built from pairs of flat corrugated metal foils (Pabst *et al.*, 2017). Efficiencies of 80% with air outlet temperatures of 800°C were reported from experiments conducted with an incident radiative power of 500 kW under on-sun conditions. The second study proposed the addition of a staggered pin-shaped micro-structure, additively manufactured in a Titanium-Aluminium alloy, to the aperture plane of the ceramic absorber (Capuano *et al.*, 2017). Operation under volumetric effect conditions was numerically predicted for such geometry, but current manufacturing limitations only allowed for the experimental assessment of a 3:1 scaled-up counterpart.

Another key aspect in the operation of OVARs is the dust deposition in pores or straight channels, which needs to be addressed for their envisaged sustained operation in arid deserts. An open volumetric air receiver design with in-situ cleaning provision is provided by Sharma *et al.* (2015a,b). This assumes that a dust may be deposited or transported through straight channels at a certain mass flow rate of air. A common concern in OVARs is flow instability at a high temperature, which results from local variations of air properties in the receiver flow field. Highly non-uniform heat flux distributions are most likely to promote such a phenomenon. In particular, centrally located absorbers subject to the usual Gaussian type distribution are the most prone to flow instabilities. Moreover, dust deposition may trigger flow instabilities and cause them to occur at a lower radiative heat fluxes. This is attributed to a higher flow resistance causing a lower local mass flow rates of air in the partially blocked channels. The deposited and transported dust may be collected using an external device.

In this paper the aspects of (a) thermal efficiency measurements, (b) flow stability in a straight channel and (b) dust deposition in absorbers are presented. Thermal efficiency measurements conducted on nine monolithic honeycomb absorbers, manufactured in siliconized silicon carbide and with square flow channels, are presented. The effects of two geometric parameters on their thermal conversion efficiency have been investigated: Flow channel width (which affects their cross-sectional porosity as absorber wall thickness is set by the extrusion manufacturing procedure), and absorber length. The results and conclusions later discussed are directly applicable to a modular receiver concept such as that of the HiTReC-SolAir system. Experimental measurements presented here also demonstrate aerodynamically stable flow conditions across the absorbers entire range of operation. For analyzing the flow instability a recently developed pressure-drop correlation for a circular straight channel based absorber is employed. The effects of dust deposition on the heat transfer in circular and square shaped straight channels are also presented.

Aerothermal Experimental Evaluation of Monolithic Honeycombs

Experimental Apparatus

The experimental measurements of thermal efficiency discussed in this paper have been conducted at the IMDEA Energy Institute. The laboratory-scale calorimetric facility and its associated techniques were described by Luque *et al.* (2018). A schematic diagram is given in Fig. 1. Incident radiation is provided by a high flux solar simulator, composed of a single 7 kW_e Xenon-arc lamp (providing 1.2 kW_{th}) and a truncated ellipsoidal reflector that concentrates light onto the test section. The experimental facility, in turn, consists of a radiation homogenizer, a calibrated gas supply system, a working section where absorber samples are housed and instrumented, and inlet and outlet flow conditioning modules. The facility employs a blowing fan upstream of the working section, which avoids the need for a heat exchanger downstream of the absorber sample, and is modular in design, which allows for a rapid interchangeability of test components and instrumentation. Careful alignment of the absorber aperture with the optical axis of the high flux solar simulator is achieved by employing a high precision cross level laser pointer.

A water-cooled radiation homogenizer of square cross section is situated between the inlet module and the working section, exactly at focal point of the high flux solar simulator. This transforms the radiation flux density profile provided by the ellipsoidal reflector (approximately Lorentzian) to a uniform distribution on the absorber aperture, which leads to the homogeneous heating

Fig. 1 Schematic diagram of the new experimental facility, with its main constitutive blocks labelled.

of the sample. The intensity of the incident concentrated radiation beam can be adjusted by metal wire grids, employed as attenuators. The inlet module is sealed by a five-millimeter thick quartz glass window.

The facility employs a dedicated instrumentation system with 42 measurement channels, including a mass flow controller, a calibrated 50 mbar differential pressure transducer (measuring between the inlet and outlet of the working section) and a set of 32 K-type thermocouples with 0.5 mm diameter Inconel sheaths. Experimental measurements conducted include absorber solid temperature distributions along its depth, air inlet and outlet temperatures, mass flow rate, pressure drop, incident radiative heat flux distributions and overall thermal efficiency. Heat flux distributions at the homogenizer inlet and outlet planes were measured with a Gardon radiometer, traversing both planes by means of an automated motion control mechanism. To within 95% confidence, the uniformity of the irradiance map at the absorber front face is $1016.4 \text{ kW/m}^2 \pm 20.1\%$, measured over an aperture area of $28 \text{ mm} \times 28 \text{ mm}$, and with an overall power of 782.7 W.

Monolithic Configurations Investigated

Experimental thermal efficiency measurements conducted on nine monolithic absorbers are presented. The effects of two geometric parameters on efficiency were investigated: Porosity and absorber length. Absorbers are grouped into two families of different cross section: Type I and Type II. Four overall absorber lengths were tested within each family, plus a reference monolith which constitutes the ninth sample (Luque *et al.*, 2017). Frontal photographs of absorbers belonging to both Type I and Type II families are shown in Fig. 2, together with a photograph of the baseline geometry. They all consist of square-cell monolithic honeycomb modules, manufactured from siliconized silicon carbide (SiSiC). Absorber lengths tested in both Type I and Type II families were 25 mm, 50 mm, 75 mm and 100 mm. The objective was to measure the influence of flow passage width and overall length on overall thermal efficiency. Wall thicknesses were generally kept as low as possible without compromising structural strength.

Flow channel cross-sectional areas in the Type I absorber family are of approximately $1.16 \text{ mm} \times 1.16 \text{ mm}$ (with a porosity of 67.7%), of $0.56 \text{ mm} \times 0.56 \text{ mm}$ in the Type II family (with a porosity of 41.4%), and of around $2.17 \text{ mm} \times 2.17 \text{ mm}$ in the reference monolith (the porosity of which is 61.4%). All other parameters being equal, absorbers with lower porosity will generally shift the radiation absorption profiles towards the front and will be better at conducting heat due to their increased solid volume. Reynolds number, and thus convective heat transfer coefficients, depends on flow channel width, but for the laminar regimes found in volumetric absorbers, the effect of having larger wetted areas is generally predominant.

Type I and Type II absorber families were manufactured by Ibiden Co., Ltd. (Japan), whereas the reference monolith was manufactured by Saint-Gobain Ceramic Materials (Germany). Besides their geometric differences, it is important to note that, at room temperature, the thermal conductivity of the Type I and II monoliths was around $27 \text{ W m}^{-1} \text{ K}^{-1}$, whereas for the reference monolith it was approximately $160 \text{ W m}^{-1} \text{ K}^{-1}$. In both cases, these values decrease by up to a factor of 4 when the samples reach 1000°C during operation – a feature of the behavior of this material that is detrimental to achieving a volumetric effect in monolithic configurations. The benchmark SolAir 200 absorber aperture, a similar monolithic configuration tested under on-sun conditions (Télez, 2003), is geometrically closest to the Type II absorber family.

Thermal Conversion Efficiency Measurements

Steady-state temperature and mass flow rate measurements were acquired, and thermal efficiency calculated, for the nine monolithic absorbers. In a typical test run, the facility would be operated at a range of decreasing mass flow rates for a given

Fig. 2 Frontal photographs of the three types of volumetric absorbers experimentally assessed: Type I (left), Type II (centre), and state-of-the-art reference geometry (right). Reproduced from Luque, S., Bai, F., González-Aguilar, J., Wang, Z., Romero, M., 2017. A parametric experimental study of aerothermal performance and efficiency in monolithic volumetric absorbers. AIP Conference Proceedings 1850 (1), 030034.

Fig. 3 Typical temperature traces acquired in the experimental facility.

incident power. The flow is allowed to stabilize at each operating condition for around 30 min. **Fig. 3** presents temperature traces in a typical test run at maximum incident power. Reducing the mass flow rate causes all temperatures to rise. Curves presented in **Fig. 3** include temperatures on the absorber rear face (8 thermocouples), and air inlet (1 thermocouple) and outlet temperatures (4 thermocouples). Vertical dotted lines indicate time windows of 100 s during which steady state measurements are time-averaged at each setting for post-processing. The facility is able to produce highly stable, repeatable and well-conditioned experimental conditions.

Absorber thermal efficiencies are calculated as the ratio between the power that is transferred to the working fluid by forced convection and the incident radiative power over the absorber aperture. The amount of heat transferred to the working fluid depends on the convective heat transfer coefficient of the flow (in turn dependent on the internal flow variables and absorber geometrical features). Quantitatively, however, thermal efficiency may be expressed by the rate of enthalpy rise of the working fluid divided by the total incident power:

$$\eta_{th} = \frac{\dot{m}}{Q_0} \int_{T_0}^{T_{out}} C_{pf}(T) dT \quad (1)$$

where $\dot{m}$ is the mass flow rate, Q_0 the overall incident radiative power, C_{pf} the specific heat capacity of air at constant pressure, and T_0 and T_{out} the air inlet and outlet temperatures, respectively. A cubic-spline interpolation of experimental measurements of C_{pf} as a function of temperature has been employed in the integral (Rogers and Mayhew, 1992).

The air temperature increment between the absorber inlet and outlet planes for the Type I family is shown in **Fig. 4**, as a function of incident power per unit mass flow rate. Measurements conducted on the reference monolith are given for comparison. There is a range of $Q_0/\dot{m}$ values in which measurements show an approximately linear behavior, which is a consequence of having low temperatures in the system. As soon as absorber temperatures increase, thermal emissions (the dominant source of heat loss) cause the measured distributions to deviate from the linear behavior.

Air temperature increments are generally higher when the radiative power increases for a given mass flow rate, and vice versa. However, it can be seen that a maximum fluid temperature rise is reached in some configurations. Increases in incident radiative power beyond this maximum do not lead to higher air outlet temperatures. Forced convection is not sufficient in such cases to remove all the additional heat received by the absorber. Thermal energy is instead lost through emission and conduction losses and efficiency decreases sharply.

Corresponding thermal conversion efficiencies for Type I absorbers are shown in **Fig. 5**, as a function of $Q_0/\dot{m}$, together with values for the reference monolith. It can be observed that thermal efficiency increases with mass flow rate in all cases. This is expected as lower mass flow rates lead to lower convective heat transfer coefficients. As a result, less heat is removed from the sample and absorber wall temperatures are higher. Larger thermal emission losses are produced in this situation. For a fixed mass flow rate, efficiencies are higher for lower incident radiation levels for the same reason: The absorber remains moderately cooler and thermal emission losses are less significant.

Air temperature increments for Type II and reference absorbers are shown in **Fig. 6**, with corresponding thermal efficiencies given in **Fig. 7**. Data on both has been plotted with $Q_0/\dot{m}$ on the abscissa. It is immediately clear that Type II configurations, of smaller flow channel width, yield higher efficiencies than any of the other monoliths investigated here. Very high thermal efficiencies (above 90%) are possible, but only when convective heat transfer is significant relative to radiation absorption (and thermal conduction) in the absorber: At low values of incident radiative power per mass flow rate (around 500 kJ/kg). As mentioned before the location of efficiency maxima depends on absorber length. Absorbers shorter than the optimal length do not exploit convective heat transfer to the full, whereas longer ones incur in larger thermal losses once convective heat exchange

Fig. 4 Air temperature increment between the absorber front and rear faces for Type I and reference absorbers.

Fig. 5 Thermal efficiency measurements for Type I and reference absorbers.

Fig. 6 Air temperature increment between the absorber front and rear faces for Type II and reference absorbers.

Fig. 7 Thermal efficiency measurements for Type II and reference absorbers.

diminishes as air and wall temperatures equilibrate towards the rear. For absorbers of equal length, reducing the cross-sectional porosity is seen to be beneficial in terms of overall thermal efficiency (this would enhance convective heat transfer).

Although not shown in these graphs, it is worth noting operation under volumetric effect conditions was not achieved with any of the absorbers evaluated in this study. In the best case measured, which was with absorber Type II-75 (of 75 mm length) operating in the low $Q_0/\dot{m}$ regime (at 413 kJ/kg, with a high mass flow rate), the front surface was at approximately the same temperature as the rear surface. In fact, the absorber temperature distribution as a function of depth was fairly flat in this case. Lowering the mass flow rate from this operating condition caused the front surface temperature to become significantly hotter than the rear. The thermal efficiency was 91.7% in this case, air outlet temperature 739.7 K and mean absorber temperature 799.5 K, approximately. Thermal efficiencies of over 90% are obtained with this absorber up to an incident power per unit mass flow rate of 551 kJ/kg.

Numerical Analysis of Flow Instability and Dust Deposition

Even with the volumetric or more so with the non-volumetric heating the desired stable flow limits a high temperature (Kribus *et al.*, 1996; Pitz-Paal *et al.*, 1997; Fend *et al.*, 2005; Becker *et al.*, 2006). This is associated with the local variation of fluid properties and in particular, the offered flow resistance at a high temperature across the different absorber flow paths. The concentrated solar irradiance on the OVAR aperture is known to be quasi-Gaussian and thus centrally located absorbers are more prone to such an unwanted situation. Ways of mitigating this include using high thermal conductivity materials to reduce thermal gradients and employing mechanical flow conditioning devices such as the orifice plates. Another challenge pertaining to the operation of OVARs in arid desert regions is the deposition of dust (with a low thermal conductivity of around $2 \text{ W m}^{-1} \text{ K}^{-1}$) in the absorber channels. This is likely to limit its installation in such areas of high potential, worldwide and in particular the Thar-desert of India and the great desert of Middle-East. The deposition and dust removal process were analyzed by Singh *et al.* (2016). The possible consequences of dust deposition are (a) flow instability even at a low heat flux concentration, (b) local or wide-area hot spots and (c) eventual failure of OVAR. Considering these aspects, this section provides further theoretical insights into the observed stable flow in a straight flow channels, with and without dust deposition, and an analysis of the detrimental effects of the dust deposition in absorber channels.

Flow Instability Analysis

The designed receiver at IIT Jodhpur along with a fabricated absorber is depicted in Fig. 8. The geometrical details and its thermal-hydraulic evaluation is already reported with Sharma *et al.* (2015a,b).

The straight channel based absorbers offer a low pressure-drop and are less prone to the dust deposition, which is adopted in the OVAR reported here. There are a number of correlations to predict the pressure-drop (Δp) across the foam-type absorbers, which may not be applicable for straight channels see e.g., Edouard *et al.* (2008). Therefore, several experiments and detailed analysis are performed (Singh *et al.*, 2018) to deduce a realistic correlation for Δp across the absorber depicted in Fig. 8:

$$\Delta p = k_p \times \frac{\rho_f v_p^2}{2} \text{ with } k_p \approx 179.25 Re_p^{-0.588} \quad (2)$$

where, k_p is the pressure drop coefficient, ρ_f is the density of air, Re_p is Reynolds number based on channel diameter (d_p) and v_p is the average speed of air inside an absorber straight channel. The derived correlation using a least square based curve-fit in terms of Re_p , includes the effect of porosity, flow and fluid properties. The correlation is based on experiments/computations under

Fig. 8 The open volumetric air receiver at IIT Jodhpur (a) with a fabricated cylindrical absorber (b).

Fig. 9 Comparison between (a) the derived correlation for pressure drop at different temperatures (b) analyzed Δp^2 with clean and partly blocked straight channel.

ambient condition and is validated (Singh *et al.*, 2018). Further, a comparison between the computed and the correlation based Δp is shown in Fig. 9(a) with the applied different uniform heat fluxes as boundary conditions up to a $Re_p < 300$. This shows that (a) the Δp increases and T_{out} decrease at high Re_p , (b) the derived correlation compares within 10%–25% with the performed simulations for a T_{out} up to 900 K, covering the range of interest. Thus, Eq. (2) is realistic and the correlation is used for flow stability analysis at a high temperature and a low Re_p with the circular straight channel based absorber.

For flow stability analysis the quadratic pressure difference across the absorber is deduced following (Becker *et al.*, 2006; Fend *et al.*, 2005) and is presented in Eq. (3). This excludes the presence of dust, but it may be extended with the same in order to investigate whether the deposition of dust will induce flow instability at a lower heat flux.

$$\Delta p^2 = p_{inlet}^2 - p_{outlet}^2 = B' \cdot \left(\frac{q_s'' / \varepsilon T_{out} - (\Sigma) \beta \sigma T_{out}^5}{(T_{out} - T_0)} \right)^{1.412} \quad \text{where } B' = \left(\frac{179.25 R \mu_0^{0.588}}{C_{pf}^{1.412} d_p^{0.588} T_0^{0.412}} \right) \quad (3)$$

Thus, a numerical model is employed and validated with the measured values of T_{out} in the reported experiment with a uniform or volumetric-type heating by Sharma *et al.* (2015a,b). A variation of the derived expression for Δp^2 with respect to T_{out} for the clean and partly blocked straight channels with dust layer thickness up to 200 μm is shown in Fig. 9(b). The increment in T_{out} is attributed to the decreasing mass flow rate of air and thus of Δp^2 . It is inferred that for a given T_{out} , Δp^2 would then increase with dust layer thickness, or with the decreasing effective absorber porosity. Also, the deposition of dust seems not to promote flow instability in the considered absorber. These observations allow expecting a stable operation of such an OVAR in desert regions. This is inferred from Fig. 9(b) in which Δp^2 shows a usual behavior as for a stable flow condition in a partially blocked circular straight channel. Moreover, the simulated value of Δp^2 with the uniform dust layer thickness of 100 μm compares well with that of its analyzed values using Eq. (3), which lends confidence to the numerical results.

Effects of Dust Deposition on Heat Transfer

To analyze the effect of dust deposition on the heat transfer both circular and square shaped straight channels are considered. The parametric investigation includes the (a) deposited dust layer thickness and its distribution along the channel length, (b) heat flux distribution along the channel length, and (c) absorber channel geometry. Two and three dimensional computational fluid

dynamics based approaches are adopted for analyzing the effect of dust deposition on the heat transfer in circular and square straight channel based absorbers. The numerical setup is summarized in **Table 1**. This shows the considered property dependent governing equations, the corresponding numerical methods and the convergence criteria. The selected final mesh is based on a grid independence study for heat transfer in a clean straight channel. For a comparative assessment of the dust deposition effect, analyses are performed with the clean and partly blocked straight channels. The deposition of dust, in an ideal case, is treated as uniform along the length, however, in reality, non-uniform profiles are expected. To simulate these different conditions, both a uniform thickness of dust layer (UDL) and a non-uniform thickness of dust layer (NDL) are studied. **Fig. 10** schematically depicts the circular and the square shaped absorbers. An axisymmetric computational model is adopted for the circular absorber, whereas a three-dimensional model is needed for the square absorber. The diameter and length of a circular straight channel are 2 mm and 25.4 mm, whereas the corresponding dimensions in case of a square straight channel are 2.17 mm and 50 mm. The latter is in line with the SolAir 200 geometric configuration (Téllez, 2003).

In **Table 1**, $I(z)$ is the heat flux as a function of axial position along the streamwise direction, I_0 is the irradiance at the front surface ($z=0$), and ε is the porosity of an absorber. The radiation based heat loss from the front surface of absorber is introduced as a boundary condition using user-defined functions.

The schematic in Fig. 11 depicts (a) the volumetric heating with a constant heat flux on the absorber surface and (b) a typical field condition with a non-uniform heat flux along the axial direction, adopted from Roldán *et al.* (2014) and implemented as a user-defined function. Different cases are analyzed with a thickness of dust up to 200 μm , which is equivalent to the four successive dust layers of 50 μm each (Yadav *et al.*, 2014). Both absorber channels are subject to the same Δp as a boundary condition.

Circular straight channel

For the two-dimensional numerical simulations with a circular straight channel, a total pressure of 15.8 Pa is applied at the inlet. This corresponds to a $Q_0/\dot{m}$ of approximately 200 kJ/kg, for a power of 1.03 W in a clean pore. The use of total inlet pressure simulates an operating condition in which all channels are exposed to the same suction. Therefore, the same pressure-drop is maintained even for the simulated partially blocked pore. The calculated Re_p is ca. 175, 70 and 19 for the clean, partially blocked straight channel with uniform dust layer thickness of 100 μm and 200 μm , respectively. Thus, the flow and/or thermal boundary layer development length will be shorter with the partially blocked channels compare to the clean channel. In realistic conditions, however, dust deposition will be generally non-uniform. To estimate the effect of such a distribution, simulations with NDL are also performed. The thickness is maximum (100 μm or 200 μm) at the inlet and linearly reduces to zero at the outlet, as shown in Fig. 10(b).

The simulations are performed with a single clean and partly blocked straight channel. The axial temperature variation of fluid and absorber material is shown in Fig. 12 for the considered straight channels with the uniform and non-uniform heat flux distributions. The deposition of dust on the channel surface will increase both the flow and thermal resistance leading to

Fig. 11 The schematic showing the applied (a) uniform and (b) non-uniform heat flux. This is depicted by arrows of an equal and the decreasing length along the straight channel-length.

Fig. 12 Axial temperature profile of fluid and solid with uniform dust layer thickness (UDL) and with non-uniform dust layer thickness (NDL) in an OVAR with circular straight channels.

Fig. 13 (a) Axial temperature profile along the centre line of absorber solid and fluid with UDL and a uniform heat-flux distribution with reference square absorber. Reproduced from Luque *et al.* AIP Conference Proceedings 1850 (1), 030034. (b) Variation of solid temperature along the longitudinal direction a clean and partly blocked channel at the central plane.

an elevated air and absorber material temperature. This can be easily inferred from the decreasing Re_p with the increasing thickness of uniform dust layer for the same applied pressure-drop. Therefore, a higher pressure-drop is required to maintain the same flow rate or Re_p in a partially blocked channel in compare to its clean counterpart. This is also evident from the analyses that show substantial rise in temperature with the partially blocked channel in comparison to its clean counterpart. The temperatures of solid and air increase with thickness of the dust layer, as expected. The modeled single circular channel with the applied UDL shows a temperature rise of about 150 K and 580 K for a dust layer thickness of 100 μm and 200 μm , respectively. Whereas with NDL a rise of about 40 K and 150 K is obtained for the deposited dust layers. This is attributed to the decreasing mass-flux for the same pressure-drop, which is confirmed by a shorter thermal development length and is depicted by the dotted vertical lines in Fig. 12(a). Thus, it is concluded that dust deposition is not only detrimental to operation but increases parasitic losses.

Square straight channel

Numerical simulations are also conducted in order to assess the effects of dust deposition on the heat transfer in monolithic absorbers with straight flow channels. The aim was to extend the analysis to a geometrically similar configuration viz. SolAir 200 absorber. The uniform heat flux boundary condition was employed on the absorber surface for simplicity. In this case, an input power of 6 W and a total inlet pressure of 151 Pa leads to the same operating condition viz. $Q_0/\dot{m}$ of 200 kJ/kg. For both the clean and partially blocked absorber channels, the atmospheric pressure is set at the outlet. Also, the radiation based heat loss is incorporated at the front side of the channel using the user-defined functions. Simulations are conducted with a constant heat flux boundary condition with an aim to numerically assess the effect of dust deposition on the heat transport. For a comparative assessment the same $Q_0/\dot{m}$ is maintained for circular and the square shaped channels. In the analysis the uniform dust layer thickness of 100 μm in the square channel is considered for a direct comparison with the circular straight channel.

The comparative assessment between clean and partially blocked square straight channel is given in Fig. 13, where a temperature difference of about 120 K is observed. This demonstrates the increased resistance to heat transfer from solid to air in the partially blocked channels, and the fact that dust deposition may thus limit the operating temperature of OVARs. The temperature rise in the circular and square shaped channels with the uniform dust layer thickness of 100 μm is quite comparable at the same power per unit mass flow rate. Thus, it is concluded that the effects of dust deposition are very similar in these geometrically different flow channels. In the simulations, Reynolds number is about 780 and 500 for the clean and partially blocked square channels. The approximate thermal development lengths are 85 and 50 mm in the clean and partially blocked channels, respectively. Therefore, it is concluded that the effect of dust deposition remains, practically unaffected for a given $Q_0/\dot{m}$, with the different channel geometries and for the developing or developed flow conditions. The fact that partially-blocked absorbers operating at higher temperatures is detrimental in terms of thermal radiation losses (proportional to the fourth power of temperature), which will lower the thermal conversion efficiency of the OVAR in the event of dust storms.

Innovative Solutions

Thermal efficiency measurements presented in this paper have demonstrated that a significantly larger effect of the forced convection heat transfer mechanism is necessary, with respect to the radiative mode, in order to achieve operation under volumetric effect conditions in monolithic absorbers. Some of the major challenges that lie in their operation at high irradiance and high

temperatures include: (a) the transfer of thermal energy from the external radiation-absorbing surfaces to the internal working fluid in a both effective and efficient manner, (b) the minimization of thermal losses throughout the system, (c) the attainment of a stable internal flow field for optimum convective efficiency, and (d) the optimization of the absorber thermo-mechanical behavior, both in transient and steady state conditions.

Variable porosity hierarchically-layered solar receivers (Gómez-García *et al.*, 2015; Alberti *et al.*, 2016) can address the main problems still encountered in monolithic honeycombs, where the incident radiative heat flux is almost completely absorbed in the front region. This enables an enhanced diffusion of incident sunlight and a shift of radiation absorption profiles towards the rear, which reduces thermal emission losses. An additional advantage is the augmentation of internal convective heat transfer in the receiver through a combination of aerothermal mechanisms: A gradually increasing wetted area surface, a reduction of flow cross-sectional areas (increasing flow velocities, Reynolds numbers, and heat transfer coefficients), and the generation and enhancement of turbulent flow structures within the intricate flow channels. Flow instabilities can also be avoided due to the flow field redistribution variable geometry receivers.

A set of fractal-like solar receivers have also been recently proposed, not based on variable porosity concepts, but on the repetition of elementary structures at larger scales: The SCRAP receiver (Lubkoll *et al.*, 2016), the previously cited a pin-shaped external micro-structure of Capuano *et al.* (2017), a bladed receiver (Wang *et al.*, 2016), and staggered rearrangements of tubes along self-repeating patterns (Ortega *et al.*, 2016). The SCRAP receiver is intended as a pressurized air receiver where numerous outward radial spikes are internally cooled by recirculating flow channels. The pin-shaped micro-structure is primarily intended as a frontal add-on to current open volumetric air receivers. The last two have been designed as improvements for current molten salt tubular receivers, however. All are aimed at improving light-trapping performance and move the operating point of solar receivers closer towards volumetric effect situations by minimizing emission losses.

Besides the geometrical and thermal-hydraulic aspects, the dust deposition is a challenge for implementing such a receiver in arid deserts. The analysis demonstrates that the deposition of a uniform dust layer (a) results in an elevated absorber temperature owing to an increased resistance to the flow of heat (b) will lead to a lower thermal efficiency as a consequence of higher radiation based heat losses. A cleaning solution for the in situ removal of dust from the absorber channels is proposed by Singh *et al.* (2016) using a cyclone separator downstream of an OVAR. This will lead to additional parasitic losses, and modified operational strategies are to be established as discussed in Singh *et al.* (2018). Interestingly, a uniform dust deposition is not likely to trigger instability in typical operating conditions of incident power per unit mass flow rate, which is inferred on the basis of the presented computational study. The generalization of this conclusion to arbitrarily non-uniform dust deposition distributions merits a more detailed three-dimensional numerical analysis.

Conclusions

This paper has presented a comprehensive set of numerical simulations and experimental measurements addressing some of the remaining practical challenges that exist in the operation of OVARs at a high irradiance and a high temperature. Stable flow conditions have been demonstrated in siliconized silicon carbide monolithic absorbers for air outlet temperatures in excess of 1000 K. It was shown that reducing flow passage width was clearly beneficial in terms of thermal efficiency in these geometries. Efficiency also generally increased with mass flow rate (for a fixed incident power). Both effects were expected as they lead to higher convective heat transfer coefficients and, as a result, a higher proportion of heat being removed from the sample. Lower thermal emission and conduction losses were produced as a result (forced convection is the only physical mechanism that increases the enthalpy of the working fluid).

With respect to absorber lengths, it was shown that an optimum value generally exists, which may be found by calculating the relative importance of thermal losses with respect to heat exchanged through forced convection. The optimum was typically achieved at low values of radiative power per mass flow rate (around 500 kJ/kg), leading to thermal efficiencies over 0.9. This would require approximately 2 kg/s of air per MW of incident radiative flux for this type of monolithic receivers, which is broadly in agreement with data presented in on-sun experiments for the state-of-the-art SolAir 200 geometry.

Current alternatives being developed as potential replacements of monolithic honeycombs include the use of fractal-like receivers, where structures of different scales are arranged into self-repeating patterns, or variable geometry hierarchically-layered receivers. In both cases, objectives sought include the optimization of radiation absorption and penetration into the solid volume, the achievement of directional thermal conduction, and the introduction of convective heat augmentation features. Additive manufacturing techniques are enabling the design and fabrication of highly creative components of increased functionality.

Such absorbers also mitigate the risk of thermally induced flow instability at the very high operating temperatures that are currently sought. However, special provisions may need to be made for operating such an absorber with in situ cleaning in geographical regions where dust deposition is significant. Numerical simulations presented in the paper showed a temperature increase of about 120–150 K in a single absorber channel at typically low values of radiative power per unit mass flow rate of around 200 kJ/kg (and the effect can be expected to be worse in situations of higher incident power per unit mass flow rate, as found in actual on-sun operating conditions). The analyses revealed that the geometry and flow conditions may increase the heat transfer deterioration on account of the dust deposition. This also has a detrimental impact in terms of increased heat loss and reduced durability.

Introduction

The culture of cultivating vineyards across the Balkan Peninsula and the Mediterranean Coast was introduced by Thracians, Phoenicians and Greeks. Serbia is among the countries that have vineyards with the ideal conditions for the cultivation of quality wines. Wine experts consider that, depending on the composition of the land, terrain and climate – the Serbian vineyards are among the best in the world. The vineyard region is a broadly defined geographical area with similar climatic and soil conditions that affect organoleptic properties of wines produced on the territory of the country, and with a similar choice of varieties.

According to the written historical data, Orahovac vineyard was known for growing vines even in the Middle Ages. However, the archeological data found indicate that the vineyards existed even before the new era. Numerous archeological finds show that Metohija is one of the oldest wine regions. The cultivation of grapes has always been concentrated in the region of Metohija and Podrimlje, around Prizren, Velika Hoča, Orahovac, Suva Reka, Đakovica and Peć. Viticulture experienced its flourishing in medieval Serbia, during the Nemanjić dynasty. Many Serbian monasteries established their metohos in Metohija ([Fig. 1](#)) (the hilly region of Beli Drim was named Metohija), in which they produced grain, grapes, wine and other products for the needs of churches and monastery fraternity. The highest number of viticulture methos were in the area of Orahovac and Velika Hoča, in which they were produced the famous “Podrumsko crno vino” (engl.Cellar red wine).

Grapes, from which the wine is made, the winemaker produces as an artwork. He designs the taste and is focused on customers who estimate the overall quality of the wine ([Lapsey and Moulton, 2001](#), p. 207). Wine has a great ritual significance in many of the world's largest religions and cultures, and it is an important part of the economy and trade. Wine is one of the oldest fermented products, and it is also a mass-produced, commercialized and studied product of fermentation ([Hutkins, 2006](#), pp. 349–350). Metohija region covers the western and southwestern part of the province, which is surrounded by Mokra Gora from the north, Čakor and branches of Prokletije from the west, Kamnik from the southwest and by Shar mountain from the south. Only one vineyard region was established in the entire territory. This region is known as the Kosovar vineyard region. Within the region, there are two sub-regions: northern and southern. Within the northern sub-region there are vineyards of Pec and Istog. Within the southern sub-region there are the following vineyards: Šakovac, Orahovac, Prizren, Suhareč and Mališevo ([Fig. 2](#)).

Spreading

The South Metohija region extends on the terrain in the southwestern part of Kosovo and Metohija, which is on the territory of South Metohija.

Included Municipalities

The South-Metohija region includes the territory in the municipalities of Djakovica, Orahovac, Prizren and Suva Reka.

Area of the Region

The South-Metohija region occupies an area of 92110.99 ha, where it is the largest.

Spreading

Orahovac vineyard extends into the central part of Metohija from the Beli Drim to Orahovac.

Included Cadastral Municipality

Orahovac vineyard includes parts of the cadastral municipalities of: Kramovik, Petković, Koznik, Pusto Selo, Sanovac, Drenovac, Orahovac, Velika Hoča, Zočište, Opteruša, Zrze, Gedža, Radoste, Ratkovac, Bardosan, Marmule, Doblibare, Meća and Crmljane, as well as cadastral municipalities of Retimlje, Mala Hoča, Nogavac, Velika Kruša, Rogovo II, Poluža, Bratotin, Vranjak, Našpale, Gornje Potočane, Donje Potočane, Stopnić, Bela Crkva, Brnjača, Celina and Brestovac.

There are significant differences in climatic and soil conditions for vineyards or subregions. The largest part of the vineyard area is located around large processing facilities in Orahovac, Prizren, Mala Kruša and Suva Reka.

Fig. 1 The South Metohija region. *Source:* Wine Guide.

Fig. 2 The Orahovac vineyards. *Source:* Wine Guide.

Starting from Metohija, which is the cradle of Serbian viticulture, the cultivation of the wine was spreading and varieties were transferred to other areas of our country. The wine trade is regulated in the Charter of emperor Stefan Dušan (1355). There is the mention of the villages of Gornja and Donja Hoča (today known as Velika and Mala Hoča) near Orahovac. The production and quality of the wines were famous outside the border of this region. The fullness of this wine is best illustrated by the folk tradition that the wine of this region could be worn in a scarf. Wine intertwines with the history of man from the very beginning. Wine intertwines with the history of man from the very beginning.

At the end of the nineteenth century wine was affected by grape vine parasites – powdery mildew, downy mildew and phylloxera – which at the beginning of the 20th century infected the vineyards of Metohija. The first reconstruction of the destroyed vineyards started around 1920 in Metohija and the utilization of wine rootstock “*riparie portalis*” and “*rupertis du lot*” for grafting grape varieties. Some of these vineyards still exist. Among them, the main variety is Prokupac, and can also be found: smederevka, šasla, plovina, hamburg, afuz-ali, red and black drain, etc.

After the Second World War, viticulture in the Orahovac area was again experiencing its true bloom. Then, in the social and private sector, new vineyards were being erected and they were fundamentally changed a new assortment of varieties. They introduced new methods of cultivation and vineyard cultivation technologies. More and more varieties were produced for quality and top quality wines, such as: game, Italian Riesling, Burgundy, County Riesling, Sauvignon, Semillon, Merlot, Vranac, Cabernet Sauvignon, Cabernet Franc, etc. New substrates are introduced: kober 5BB, ŠxB41B, SO4, etc.

The holder of the grape production in the Orahovac vineyard was a socially-owned enterprise for the production and marketing of alcoholic beverages of PKB “ORVIN” in Orahovac, which had over 1000 ha of modern vineyards. It was equipped with the modern basements with a capacity of 4500 wagons, as well as with highly skilled personnel and workers in the field of viticulture and wine-growing. In these basements were produced table tops, quality and top quality wines, which carry all the quality

characteristics of cultivated varieties and specificities of this region. In these basements were produced table wine, quality and top quality wines, which contain all the quality characteristics of cultivated varieties and specificities of this region.

These wines have gained its reputation with its quality, not only for consumers throughout our country, but they have been highly appreciated and known abroad as well. However, today vine growers in this area are facing enormous problems in the production and marketing of wines. Recently, the hailstorm in the Orahovac area has destroyed about 50% of the grapes, and it will surely cause further increase in production, because it is necessary to extract the vineyards in order to protect them from rot.

Today, one of the more representative wines of this region has a storage capacity of 45,000 L of wine and an annual production of about 15–20,000 L. The winery also has other necessary equipment: crushers, pressing machines, vinificators, pumps, filters and its own laboratory. The winery provides technical assistance in the supply of equipment for use as well as advisory assistance in wine production to small winemakers from the Orahovac and Velika Hoča enclaves. However, the problem of wine placement still remains the imperative for the survival of this and all other wineries of this region.

Given the large number of brands, the selection and purchase of wine is a complex task for the consumer. The quality of the wine is not known until the bottle is opened and the content is tested. Therefore, the moment of selecting a particular wine from the perspective of what is happening in the consumer's mind and what is the main reason for buying a particular wine is a very important in the marketing of wine (Fernandes Ferreira Madureira and Simões de Sousa Nunes, 2013, pp. 75–77). It should be noted that the one-time purchase of a bottle of wine is not the ultimate goal of the manufacturer. Its aim is to obtain loyal customers (Hussain *et al.*, 2007, pp. 49–51).

Small Enterprises and Internet Advertising

The significance of promotion is great nowadays, because it has to radiate diversity and quality service that can compete with all global competitors. The Internet is one of the fastest growing media today. In most European countries, wine production is higher than consumption, which contributes to the imbalance between supply and demand. Companies that appear on the Internet are more seen by customers, they are better targeted, informed, sophisticated and they are better technologically adapted to the younger population (Sutherland and Sylvester, 2000, p. 239).

If we add this information to the primary goal of business communication, we will come to the comprehensive definition of well-known authors, (Kotler and Keller, 2012, p. 478): "Advertising is an audio or visual form of marketing communication that employs an openly sponsored, nonpersonal message to promote or sell a product, service or idea. Sponsors of advertising are often businesses who wish to promote their products or services through various mass media, including printed media, Radio, Television, telephones, cable, satellite and wireless networks, electronic media, billboards, signs and posters." A little later, Kotler and Armstrong (2014, p. 454) represent a slightly different definition, which includes paid advertising components, "Advertising is the communication of the value of a company or brand through the use of paid media and for the purpose of informing, convincing and reminding consumers."

The number of Internet users worldwide and in Serbia is growing rapidly. More than 2.4 million citizens use the Internet on a daily or almost daily, which is 300,000 more in 2012 than in 2012, according to the Statistical Office of the Republic of Serbia (SORS). In Serbia, more than 59.9% of households have a computer, while the Internet connection has 55.8%. The number of households with a computer is 4.7 percentage points higher than last year, and the number of Internet connections increased by 8.3 percentage points.

Enterprises sometimes advertise a product or service, which increases consumer awareness of the company, creating an apparent picture of demand, and thus encourages traders to accumulate stocks or even discourage a certain segment of consumers from purchasing in order to maintain a certain reputation (Brierley, 1995).

When it comes to the enterprises in Serbia, more than 99.6% of them have an Internet connection, which is 1.9 percentage points more than in 2012, according to the Statistical Office of the Republic of Serbia (SORS). According to the survey on the use of information and communication technologies in Serbia, in 2013 the website had almost three quarters of the enterprises with an Internet connection (73.8%). The computer owns 59.9% of households, while the Internet connection owns 55.8%. The analysis of enterprises by size shows that all large and medium-sized enterprises have Internet access, while among small enterprises 99.5% have Internet access.

The definition of micro, small and medium-sized enterprises often changed in the past, so that in different countries there are different definitions and approaches (Kotler and Armstrong, 2014, p. 454). In addition to these two authors, the authors (Bridge *et al.*, 1998) point out that there is no unique, clear definition of small and medium-sized enterprises. Basically at the same time, there are three subgroups of small and medium-sized enterprises: micro, small and medium enterprises. Small enterprises in European Union countries account for 99% of all enterprises (European Commission, 2014).

With the increase of Internet users, the number of the Internet advertising also increases. The Internet offers the market and consumers the possibility of significantly greater interaction and individualization. Individualization refers to the fact that users have control over the flow of information, which leads to opportunities for advertising and promotions that are relevant to consumers. The interaction, which interweaves with individualization, provides the bidder with a choice of information that is significant for him, while the advertising establishes two-way communication with the consumer (Shimp, 2003, p. 394). Advertising on the Internet can be easy, only if we properly use the good and weak sides of that media. Internet advertising allows reaching more people on a global scale, better focus on target groups, lower costs, easier comparison of results, and easier adoption

Table 1 Number and annual growth of Internet users from 2005 to 2014

Year	Number of users	Rate of growth in %	World population	Population growth in %	Penetration(% of internet population)
2014	2,925,249,355	7.9	7,243,784,121	1.14	40.4
2013	2,712,239,573	8.0	7,162,119,430	1.16	37.9
2012	2,511,615,523	10.5	7,080,072,420	1.17	35.5
2011	2,272,463,038	11.7	6,997,998,760	1.18	32.5
2010	2,034,259,368	16.1	6,916,183,480	1.19	29.4
2009	1,752,333,178	12.2	6,834,721,930	1.20	25.6
2008	1,562,067,594	13.8	6,753,649,230	1.21	23.1
2007	1,373,040,542	18.6	6,673,105,940	1.21	20.6
2006	1,157,500,065	12.4	6,593,227,980	1.21	17.6
2005	1,029,717,906	13.1	6,514,094,610	1.22	15.8

of changes (Taylor, 2013, p. 11). At the same time, advertising on the Internet also shows certain weaknesses, such as overcrowding of pages with ads, short lifespan of advertisements, and lower rates of advertising of those ads on Television, because users should not see ads which are not interesting to them (Clow and Baack, 2007, p. 251).

The advantages of small enterprises in comparison with large enterprises and companies are presented below (Bridge *et al.*, 1998):

- Flexibility, which means they are able to respond quickly to new business opportunities, and timely transform innovative ideas into market products.
- Lack of bureaucracy, entrepreneurial managers responds quickly to new opportunities and they are willing to take the risk.
- Efficient and informal communication network that enables quick response in solving internal problems and providing opportunities to quickly adapt to changes in the surroundings.
- Good customer adaptation as well as a good knowledge of their needs and knowledge of problems in a particular working environment and offer them additional services.
- Support for large enterprises.
- Efficient production of goods and provision of services.
- Creating new jobs.
- Small quantities of supplies that are well adapted.
- Increasing efficiency, reducing costs.
- Better information gathering.
- Encouraging competition.
- Possibility of specializing in the market segment of certain products or services.
- Introduction of innovations.

In 1995 access to the Internet had only 1% of the world's population, while nowadays access has about 40% of the world's population. The number of users increased from more than 10 times between 1999 and 2013. Billions of beneficiaries were reached in 2005 and the second billion in 2010. By the end of 2014, Internet access had 3 billion people (Internet Users, 2014).

The rapid advancement of the Internet is reflected in the following numbers. The number of the Internet users reached the first billion in 2005, the second billion in 2010 and the third billion in 2014 (Internet Live Stats – Internet Users, 2016). It is stated in some institutions reports that by 2020, the number of Internet users via mobile devices and tablets will increase to 7.6 billion (International Telecommunication Union, 2014). If these forecasts are made, the number of Internet users will be above the current world population in less than 5 years (Table 1).

More than 3 billion people worldwide are online daily in search for products, entertainment and friends. This brought drastic changes in consumer behavior and in the ways in which organizations perform marketing activities and consumers activities of business marketing (Chaffey and Ellis-Chadwick, 2016). The modern marketing communication approach therefore requires a good knowledge and understanding of the consumers' needs and their habits, as well as understanding of the ways they want to communicate with the organization and the content they want to see (Stone and Woodcock, 2014).

Famous authors, Chaffey and Ellis-Chadwick (2016), are named an approach that enables communication with consumers in the digital world, digital marketing. Digital marketing can be seen as a kind of digital equivalent of the combined marketing communications, which includes all elements of classical marketing. The authors Kotler and Armstrong (2014) emphasize the need for classical advertising on the pages and the demand for communication with clients via e-mail, the use of websites and multimedia presentations of companies, products and services for building relationships and interacting with clients through social media.

Some authors point out that the use of digital technologies for marketing purposes is no longer a choice, but the only way for companies to maintain a competitive advantage, Gartner pointed out already in 2012, when on the basis of several studies he predicted that by 2017, the marketing director will invest more in Technology as IT director (McLellan, 2012). This is confirmed by recent research, which shows that 98% of retailers agree not to talk about digital marketing, but marketing in the digital world

(Gartner, 2015). In addition, experts estimate that marketing has become one of the most technologically dependent business functions (Brinker and McLellan, 2014).

Disadvantages of small businesses compared with large companies are shown below (Bridge *et al.*, 1998):

- Small enterprises run by the owners themselves, who, despite the average higher education, do not have marketing skills. There is also the absence of functional managers and rare creation of specialized departments. This can be a problem, as a leading company usually performs all the work they do in a large company specializing in specific areas, such as financial director, production director, and marketing director.
- Lack of people with appropriate education and work experience is one of the biggest obstacles for the growth and development of small enterprises. Difficulties in hiring skilled workers usually occur because small enterprises generally pay lower wages than large companies and provide fewer extra special benefits, give less social security and job security, and offer few opportunities for advancement.
- Poor use of human resources in the company can be caused by financial concerns for the survival of small enterprises, which do not encourage the creation of training and employee development opportunities.
- Great difficulties in obtaining financial resources, such as loans from banks and other institutions necessary for growth. Some entrepreneurs are sometimes able to cope with the growing challenges of the company. Innovation can be a big financial risk. Small businesses quickly become victims of financial indiscipline because they do not have much capital. Given the limited funding and reserves associated with low borrowing capacity, small enterprises are very vulnerable during the economic downturn.
- Poor conditions with their suppliers for alternative and lesser purchases on the market e.g., lower prices, delivery deadlines, and other terms. At the same time, small enterprises largely depend on their suppliers, among other things, because they can not produce many components and perform all services necessary for their activities.
- Small enterprises are more likely to achieve high economic efficiency, because they can not take advantage of the big company's privileges, which, for example, have a discount for the purchase of large quantities, using a sophisticated marketing and distribution system.
- Obstacles and difficulties in acquisition and exploitation of modern technologies. It is often done with inappropriate or incomplete information. In order not to increase the cost of doing business, it is often saved on the information systems.
- Lack of time or resources to identify and use external sources of scientific and technological knowledge.
- Small enterprises are usually limited to one product or a very narrow range of products and services.
- Problems with patent systems. They can not afford the time or costs that this process requires.
- They can not often deal with complex rules.
- Poor state support and support for small businesses.

Small enterprises with their characteristics are designed and are in a good position to adapt to the needs of consumers and to the new technologies. Compared to larger companies, their flexibility has resulted in easier and faster adaptation for less administrations and hierarchies (Payne, 2005).

In a small company, where the budget for advertising is lower, there are wonderful opportunities for online advertising. Famous author wrote at the time of advanced advertising in traditional media: "If you are in doubt, do it yourself. Be brave! You can not?! Advertisement [...]! Just try! After 4–5 messages, you will see: Advertising is paid off at once!"

As the famous author Neti (2011) presented in his works – about 75% of small enterprises have their own web pages on social networks, of which 69% are regularly updated their website, and 54% monitor consumer responses.

In the European Union countries, small and medium-sized enterprises account for 99% of the total number of enterprises, of which 20% are involved in export activities. Therefore, the internationalization of business for most small enterprises is essential for the survival of the enterprises themselves (Pleitner, 1997; Daily *et al.*, 2000).

Advantages of Online Advertising

Zeff and Aronson (1999, p. 13) have presented four main advantages of the Internet over other media:

- Targeted communication.
- User monitoring.
- Presence and flexibility.
- Interactivity.

In relation to Zeff and Aronson (1999, p. 13), in the literature it can be found that the advantages of the Internet are more analyzed and that other advantages are also added:

- Internet advertising is effective for direct marketing as well as for branding.
- Internet advertising is easy to measure.
- Internet advertising can be improved.
- Internet advertising is "laser" accurate.
- Internet advertising can be monitored and predicted.

- Internet advertising is relatively cheap.
- Internet advertising gives fast and lasting results.
- Internet advertising can be a type of automation.

Disadvantages of Online Advertising

Besides of advantages, we must be aware of some of the disadvantages that the Internet brings us as a medium of advertising. Clow and Baack (2007, p. 251) point to 4 weaknesses.

- Saturation.
- Short lifetime of the ad.
- Limited range.
- Low interruption rate.

In addition to the abovementioned disadvantages, the following shortcomings may also be mentioned:

- Uneven measurement, measured results and campaign efficiency can be different, which makes it impossible to compare data;
- Insufficient information control, because we know that a large amount of online information can be inaccurate or out of date; companies must ensure that their ads are always interesting and current; otherwise they may lose their users;
- Costs that are on a simple internet site and communication channels are relatively low, in more complex solutions can be significantly higher because they require higher maintenance costs;
- Service speed can also be reported as a problem; powerful graphics and applications that a user loads into a computer can lead to slow flow of information, which can dissuade users from browsing the web site;
- The problem is mistrust of users; most users still do not trust electronic business and the Internet does not feel very safe to them;
- A major advertiser problem is a variety of messaging software, which prevents certain ads from appearing on the Internet.

Definition of Online Advertising

Kotler (2003, p. 250) defines advertising as well as any paid form of impersonal presentation and of promotion of ideas, goods or services from a known purchaser. It is a paid form, which means that there must be a place and time for an advertised paid space. As impersonal form, advertising covers mass media (e.g., TV, radio, newspapers) that allow the transmission of messages to a large group of individuals at the same time. Due to the impersonal nature of advertising, advertisers can not receive immediate feedback from the recipients of the message. Advertisers must, before sending the message, predict that recipients will understand and respond to it (Belch and Belch, 2003, p. 16). Richards and Curran (2002) define the notion of advertising as a paid form of communication, the purpose of which is to persuade the recipient to take action now or in the future.

Zeff and Aronson (1999, pp. 11–12) define advertising as an attempt to expand the information in order to influence the transaction between buyer and seller. Internet advertising allows you to display your ads that are tailored to individual users according to their interests. Internet advertising is therefore a convergence between traditional advertising and direct marketing. Internet advertising can be defined as any form of communication that meets the definition of advertising and which can be found on the Internet (McMillan, 2004). At the beginning of the 20th century, it was very important to notify customers with the arrival of new types of products. Today, advertising is an important part of economic activity in all developed economies. In the advertising function, the main goal is to attract the attention of users through any media (Postma, 1999, p. 24).

World's Online Advertising Usage

Today, online advertising is one of the biggest drivers of the European digital economy, promoting industry development and economic growth through accelerated development and innovation. During 2014, 46 billion euros were invested in online advertising, of which 30.4% (30.7 billion euros) went to European publisher's funds. According to IAB data, revenues from Internet advertising in the US in 2013 amounted to 42.8 billion dollars, thus exceeding the revenue from TV advertising, which reached 40.1 billion dollars. In the last quarter of 2013, revenues from the Internet advertising amounted to 12.1 billion dollars, which is 14% more than in the third quarter of the same year, when they amounted to 10.6 billion dollars. Compared to 2012, revenue from Internet advertising grew by 17%.

Internet advertising revenues in 2013 amounted to \$ 12.8 billion, representing 30% of total revenues, which increased by 7% compared to 2012. In this category of Internet ads, banners dominate, which yield 19% of revenues, followed by video ads with 7%, enriched ads with 3%, and sponsorships with 2%. Advertising on search engines still generates the highest revenue, which accounts for 43% of total digital advertising revenue. In 2013, they amounted to \$ 18.4 billion or 9% more than in 2012 (Digital Ad Spending Worldwide to Hit, \$137.53 Billion in, 2014, 2014).

The forecasts indicate that spending on Internet advertising in 2014 amounted to \$ 137.53 billion globally, which means that there was an increase in costs of 14.8% compared to 2013 when they amounted to \$ 119.84 billion (Digital Ad Spending Worldwide to Hit, \$137.53 Billion in, 2014) (Fig. 3).

Fig. 3 Serbia within the EU (2012–2013).

In 2013, the largest share in advertising expenditure, which was 40.1%, was still intended for advertising on television. This is followed by mobile advertising with 21%. In 2014, it was mostly spent on internet advertising, which is \$ 55.7 billion dedicated to advertising on the search engines, then on showing ads with \$ 51.8 billion. The data showed that the share of spending on internet advertising would increase to 27.1% by 2016 (Lunden, 2014).

Key data and trends:

- The total value of the digital and interactive advertising market in 2013 was estimated at € 16,320,000, including advertising on mobile devices.
- The growth of the total market value was estimated at 13.41%, which means that the positive trend of double-digit growth was maintained.
- The largest growth in the previous year was due to social networking, or social media marketing (27%).
- The mobile advertising market in 2013 recorded an increase of 150%, which means that the total value of this market segment was € 380,000.
- The total value of the market continues to be the largest contributor to display advertising (50.68%) with a total net value of € 8.230.000.

Internet Advertising Forms

The first forms of internet advertising were the websites themselves. As the Internet soon became crowded with advertising sites, they were no longer enough to attract users. Advertisers needed a tool that would bring more users to the site. The first advertising models were banner and button (Zeff and Aronson, 1999, p. 23). Advertisers are constantly developing new ad formats to attract their desired customers. There are many different forms of internet advertising. Research shows that these are most common: advertising banners, pop-ups, sponsored ads, text ads, comprehensive ads, but also floating ads, wallpaper changes, online games, ad breaks, video ads and screen savers.

Users' Attitudes Towards Online Advertising

Users' attitudes towards online advertising have become a topic of discussion since the mid-1990 (Nasir *et al.*, 2011, p. 61). A study of users' attitudes toward advertising is important because advertising affects the user's attention and responses to specific ads (Alwitt and Prabhaker, 1992, p. 31). Today, most sites are flooded with internet ads, while advertisers have many forms of internet advertising, and are constantly developing new forms and methods of advertising. Site saturation with adverts, the number of existing and new opportunities for expansion and promotion of goods or services offered by the Internet, as well as the forecast that Internet advertising will continue to develop in the future - indicate the need to examine the user's attitude towards online advertising and towards different forms of online advertising (Burns, 2003, p. 18). Famous authors Rodgers and Thorson (2000, p. 43) consider that the user has a great importance in advertising. In order to examine for what purpose people use the Internet and which factors attract users and encourage them to return, they have developed a so-called model of Interactive advertising (Fig. 4).

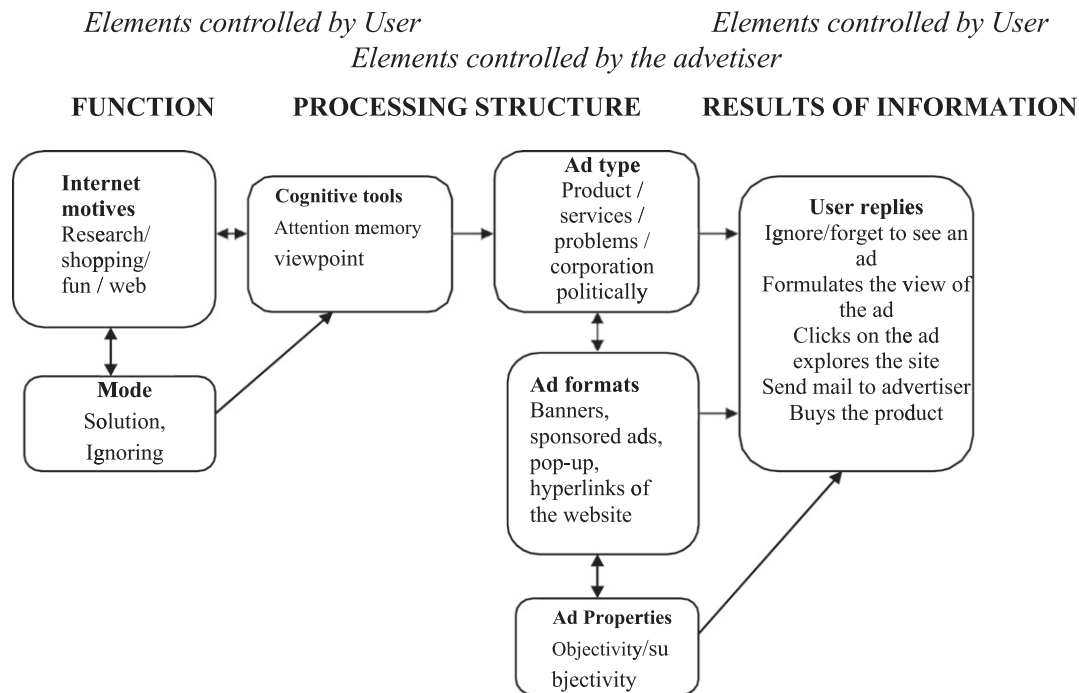

Fig. 4 Interactive advertising model.

Current Research of Users' Attitudes Towards Online Advertising

In his research, Ducoffe (1996, p. 27) found that users perceive advertising as important and informative, not too intrusive, but also not too fun. Other studies have shown that users see online advertising as a pushy (Reed, 1999, p. 25) and intrusive appearance (Li et al., 2002, p. 45). In his study, Schlosser et al. (1999, p. 43) shows a divided opinions on Internet advertising. When they were asked whether they are in favor of advertising or not, 38% of users responded that they are fond of it, 25% that they did not, while the rest was neutral. Most users see internet advertising as informative (62%), while 49% say they do not see all the ads they are exposed to. Less than half of the users (48%) trust Internet advertising. When asked how often they use advertising to help them with the purchase, 67% of users responded with-never.

In the research conducted by Previte (1999, p. 203), users generally consider Internet advertising to be informative. Most users (69%) search for information about products and services via internet ads, 48.9% of users use online ads to find products and services that interest them, while 59.5% think that in Internet advertising there are no current information. Approximately 44% of users think that internet advertising is fun, while 50% of them believe that online advertising is less pleasant than other content on the Internet. Data shows that 54.3% of users believe that internet advertising is a good thing. In general, 46.9% of users have a positive attitude towards Internet advertising.

In a study conducted by Rettie et al. (2003), it was found that users have showed a more negative attitude towards Internet advertising. According to their data, 42% of users believe that Internet advertising is annoying, 45% believe that internet advertising is a waste of time, 63% believe that online ads are boring in terms of control, 62% of them like to visit sites that are not advertised. In contrast, 13% of users never click on an ad, and 69% think that Internet advertising is acceptable when it leads them to the desired content.

Regarding the research on attitudes towards certain forms of online advertising, users perceive web banners as poorly entertaining, unobtrusive and average informative. Users see pop-up windows as boring, disturbing and least informative. On the other hand, users perceive large vertical banners as very entertaining, informative, and unobtrusive. Floating ads turned out to be the funniest, and at the same time the second most striking and least informative form of the advertisement. Advertising breaks are perceived as very entertaining, average informative and average striking (Burns, 2003, p. 162). According to Tutaj and van Reijmersdal (2012, p. 5), users view sponsored links as more informative, more entertaining and less attacking compared to web banners, but they consider web banners more visible than sponsored links.

According to the survey conducted by UK company "Respond", users mostly interfere with video ads that run when websites are loaded, while the second most striking and disturbing factor are pop-ups windows, while the third and fourth-expanding ads and ads that appear when the user sets the mouse on a particular word (Robles, 2012). Adobe's research shows that more than a third of users believe that internet advertising is inefficient, and that advertising on television is more effective than internet advertising (66%). The words boring and striking are also often used to describe online ads (Lomas, 2012).

The research on the relationship between online advertising and Internet advertising was conducted by Gemius in 2006 in some European countries. The results show that in average users consider Internet advertising as an efficient way of advertising

products and services, but also very tedious. More than half of the respondents said that their ads were annoying and that they appeared too frequently when they search the Internet. The most popular forms of internet advertising are banners and sponsored links, which shows that users prefer those types of ads that do not interrupt them and do not interfere with the internet search aggressively. Research shows that the most popular forms of advertising among the users in the Republic of Serbia are web banner ads, followed by a video.

There is also an interesting study conducted by the enterprise Insights One, which, in addition to statistics about the types of ads that are striking to users, shows surprising facts about how users respond on striking ads. Even 60% of users are logged out of receiving promotional mail, 45% ignore e-mails, 36% leave the site, 14% no longer use the advertised product, 13% stop using or buying products from the advertised company (*The Peril of Terrible Ads: Certain Display Ads Draw Ire*, 2013).

To summarize, it can be concluded that the results of individual research in a given period may vary. Some research shows that users consider online advertisements as informative and important, and have a positive attitude about them, while others show a generally negative attitude towards online advertising itself. While a clear conclusion can not be made on the basis of these studies, a self-study on how users perceive the Internet and their views on the forms of online advertising is presented in the text below.

Empirical Research

Analysis of the Research Result

Below is a presentation of the empirical research, which was conducted using the method of quantitative research, i.e., Internet interviewing. The aim of this type of research is to use the questionnaire in order to find out what is the attitude of the users in Serbia towards Internet advertising. We set hypothesis – *H1: Users generally have a negative attitude towards internet advertising.*

The results of the current research generally differ. Some research show that users generally have a positive attitude towards internet advertising (e.g., [Ducoffe, 1996](#); [Previte, 1999](#)), while others have a negative attitude (e.g., [Li et al., 2002](#); [Rettie et al., 2003](#)). As the results of recent research have repeatedly cited the negative attitude of users towards online advertising and because it is possible to notice the saturation of some internet sites with such advertisements, we anticipate that users have a generally negative attitude towards internet advertising.

This research will also reveal what are the factors that help the user when choosing and buying a particular type of wine. At the end of the research common opportunities, weaknesses, opportunities and threats of winemakers in Kosovo and Metohia were summed up through a SWOT analysis.

Sample description

The research was conducted from 01/03/2017 to 01/04/2017. Potential respondents were invited to collaborate via social networks and e-mail and were selected randomly. The poll clicked by 342 users. Of all those who started filling in the questionnaire, the questionnaire was completed by 146 users, while the 57 completed questionnaire only partially. One of the main reasons for a somewhat high number of partially filled questionnaires is probably the occasional irregular work of the 1KA tool in a particular search engine. Due to unknowingly the completion of the questionnaire was interrupted in different steps. The interviewees could not continue filling in because they were again overruled at the beginning of the questionnaire. In the further analysis only the questionnaire filled in is complete. Of all those who started completing the questionnaire, in whole the questionnaire filled 146 users, while 57 questionnaires filled in only partially.

One of the main reasons for, to a certain extent, high number of partially completed questionnaires is probably the occasional irregular work of the 1KA tool in a particular browser. Due to an unknown reason, the questionnaire was interrupted in various steps. The respondents could not continue to fulfill them, as they were again redirected to the beginning of the questionnaire. Only fully completed questionnaires are included in the further analysis.

From the [Table 2](#) it can be seen that out of 146 users, who fully responded to the questionnaire, 65.75% of them were women and 34.25% – men. The largest part of the interviewed users, which is 35.62%, is grouped among people between 30 to 40 years. The second largest age group is comprised of users from 20 to 30 years (26.71%), followed by the age group from 40 to 50 years with 18.49%. A smaller proportion of users, 15.07%, are classified as an age group of 50 years and over, and at least those are up to 20 years old (4.1%). The second largest age group is comprised of users from 20 to 30 years (26.71%), followed by the age group from 40 to 50 years with 18.49%. A smaller proportion of users, 15.07%, is classified as an age group of 50 years and over, and at least those are up to 20 years old (4.1%).

With regard to their education, most users have a completed high school or secondary vocational school (56.85%), and is followed by those with school of higher education (41.78%). The smallest part consists of users with elementary school and less (1.37%). The majority of the surveyed users that is 83.56%, are labor-active, 2.74% are labor-inactive (pensioners, etc.), while 13.70% are unemployed. One third of the respondents (32.19%) have an average net income of 55,001 to 75,000 dinars, followed by those with income of 35,001 to 55,000 dinars (31.51%), followed by those with income of 25,001 to 35,000 dinars (22.60%), while without personal income there is 13.70% of respondents.

As regards the use of the Internet ([Table 3](#)), the majority of users (69.18%) use the Internet several times a day, 16.44% once a day, 11.64% several times a week, 2.74% users several times a month. Of those who use the Internet at least once a day or more,

Table 2 Demographic significance of surveyed Internet users

<i>Demographic variations</i>	<i>Number of users</i>	<i>Percentage (%)</i>
<i>Gender:</i>		
Male	50	34.25
Female	96	65.75
<i>Age:</i>		
Up to 20 years	6	4.1
20–30 years	39	26.71
30–40 years	52	35.62
40–50 years	27	18.49
50 years or more	22	15.07
<i>Education:</i>		
Elementary school or less	2	1.37

School of higher education	61	41.78
<i>Employment:</i>		
employed	122	83.56
Inactive, retired, unemployed	4	2.74
	20	13.70
<i>Average, personal, monthly net income</i>		
<i>Income (in dinars):</i>		
25,000 or less	12	8.22
25,001–35,000	33	22.60
35,001–55,000	46	31.51
55,001–75,000	47	32.19
75,000 or more	8	5.48
Without personal income	20	13.70

34.25% of the users use the Internet on average by 1 to 2 hours per day, less than 1 h of Internet use 16.44%, 2 to 3 h use 21.23% of users, 3 to 4 h and more than 5 h 10.96% of users, and 6.16% of those who use the Internet in average for 4 to 5 h a day.

Review of the results and testing of hypotheses

In the second set of questions, users rated 16 claims on the five-step Likert scale, which are related towards user's reactions and attitudes towards Internet advertising and internet advertisements in general. These are the following statements:

Internet advertising is a good form of information

- (1) Internet advertising is mandatory
- (2) There are too many ads on the Internet
- (3) Internet advertising seems deceptive to me
- (4) I am generally fond of internet advertising
- (5) Internet ads are informative.
- (6) Internet ads are useful and fun
- (7) Internet ads are a waste of time
- (8) Internet ads are hindering.
- (9) Internet advertising helps me with purchasing decisions
- (10) I like the web site without ads
- (11) When I see an internet ad, I look closely at it
- (12) When I see an internet ad, I click on it to find more information
- (13) An internet ad often takes me to buy an advertised product/service
- (14) I usually ignore an Internet ad

The results of the research are shown in [Fig. 5](#).

The results of the research showed that out of the 146 respondents, 110 users (75.34%) think that Internet advertising is a good source of information, 83 users (56.85%) also think that Internet ads are informative. On the other hand, 88 users (60.27%) usually ignore Internet ads, 92 users (63.01%) think that there are too many ads, 99 users (67.81%) prefer websites that do not show ads. According to 70 users (47.95%) advertising is mandatory. The claim that Internet advertising helps them with the

Table 3 Internet activity of examined Internet users

<i>Using the Internet</i>	<i>Number of users</i>	<i>Percentage (%)</i>
<i>Frequency of using the Internet:</i>		
Several times a day	101	69.18
Once a day	24	16.44
Several times a week	17	11.64
Several times a month	4	2.74
Less then 1 time per month	0	0
<i>Average number of hours per day</i>		
Less than 1 h	24	16.44
1–2 h	50	34.25

purchase decision is supported by 40 users (27.40%), while 59 users (40.41%) disagree. 78 users (56.15%) find out that the Internet ads are disturbing.

Before starting to examine the main hypothesis, that is, what are the attitudes of users regarding Internet advertising in general, the direction of the claim first should be consolidated, because in some claims the reverse Likert scale is used. Coefficients of asymmetry and alignment indicate that the data sharing is not normal, for this reason was used the Kolmogorov–Smirnov and Shapiro–Wilk test in order to check the normality of data division. In this case, the null hypothesis states that data is normally distributed. If the P value is smaller than the characteristic rate of 0.05 then the null hypothesis is rejected, and if the P value is greater than the characteristic rate of 0.05 then the null hypothesis can not be rejected. Since both P-values are less than 0.05, this means that data are not normally distributed, so we use the appropriate mean value below. Before calculating the mean value, the variables were adequately decoded. Rating 0 in this example represents a negative attitude. Those ratings are combined with rating 2 (I totally disagree), and 4 (I do not agree). Rating 1 represents a positive attitude. Those ratings are a combined with

Table 4 Mean values for generalized claims about internet advertising and internet ads

Number	General claims about internet ads and internet advertising	Number		Median	Modus
		Valid	Hindering		
1.	Internet advertising is a good form of information	136	10	1000	1.00
2.	Internet advertising is mandatory	130	16	1000	1.00
3.	Too many ads on the internet *	139	7	0000	0.00
4.	Internet advertising seems to me deceptive *	119	27	1000	1.00
5.	I'm generally in favor of internet advertising	136	10	0000	0.00
6.	Internet ads are informative	132	14	1000	1.00
7.	Internet ads are useful and fun	135	11	0000	0.00
8.	Internet ads are a waste of time *	132	14	1000	1.00
9.	Internet ads are hindering *	136	10	0000	0.00
10.	Internet advertising helps me with purchasing decisions	112	34	0000	0.00
11.	I prefer the websites without ads *	121	25	0000	0.00
12.	When I notice an internet ad, I look closely at it	136	10	0000	0.00
13.	When I see an internet ad, I click on it to find the information	126	20	0000	0.00
14.	An internet ad often takes me to buy an advertised product / service	130	16	0000	0.00
15.	I usually ignore an online ad *	137	9	0000	0.00

Appendix: * For these statements was used reverse Likert scale. Rating 0 represents a negative attitude, and the rating 1 is a positive one.

rating 1 (I agree) and 3 (I completely agree). Rating 5 (I do not know) was in this case eliminated because it is neither a positive nor negative attitude.

From the [Table 4](#) it can be seen that 10 claims are negative (66.67% – in the table colored in blue) and only 5 claims (33.33%) are positive. Since users generally show negative attitudes, we can confirm a hypothesis that users generally have a negative attitude towards Internet advertising.

External Evaluation of Small Enterprises for the Production of Wine on the Territory of Orahovac and Velika Hoča

Due to the mild climate, as well as the southern exposure of the terrain around Velika Hoča and favorable soil, and the God-given landscape – is ideal for growing vines and producing excellent wines. This is why vineyards are widespread in large areas. The income from viticulture and wine trade was quite high, so emperor Dušan introduced the customs duty (in 14th century). Almost all the owners in the village had their own cellars (winery) for cultivating grapes, and the arrival of a large number of those who were in the vineyards and produced wine made it possible to raise many residences, cottages and other facilities (Monastery of Dečani, Devič of richer individuals).

Today, there is an active Dečanska vinica (winery), where the monks of the monastery of Dečani make an excellent metohistic wine, and also have private vineyards.

Winery antić-orahovac

- Winery Antić owns 90 acres,
- 50,000 to 55,000 kg of grapes are purchased annually,
- 30,000 to 35,000 L of wine are produced annually,
- 90% are redeemed by Albanians and the remaining 10% of Serbs and others,
- 2/3 black and 1/3 white wine
- the capacity of 35,000 L of wine each year.

Problems in business:

- Double VAT, double excise,
- Kosovo redeemers carry out extortion in price and the money is paid only in May of next year. This could lead to our country being overwhelmed by the fact that this Serbian winemaker is giving money to the producers immediately after the purchase. For this reason Albanians prefer to sell it to a Serbian producer.
- In 2015 the price of grapes purchase was 26–30 cents for the Vranac, which is the most purchased, because it is good for mixing, purchasing, etc.
- The selling price of white and black wine in the plastic bottle is 150–190 dinars per litre,
- The selling price is 4–4.5 Euros for a glass bottle of 0.75 L for black and white wine (38 cents a bottle, cork 50 cents, 10–12 cents labels and transport whose price depends on the destination).

Fig. 6 Significance of different factors in purchasing and selection of wine. Appendix: * 1 means “Not important at all”, 2 means “not important”, 3 represents “not important or unobserved”, 4 means “It’s important” and 5 “very important.”

- The export is mostly done in plastic bottles and glass in small quantities of 20–40 bottles in buses and vans, but not in tanks due to problems on the road by the Kosovo police, sanitary inspection, etc.
- Company “Navip” from Serbia has offered to redeem all wine production, but at 55 cents per liter, but Mr. Antić rejected because it was unprofitable for him.

Winery petrović

- Wine production and wine tourism have 15 sleeping beds that are mostly issued to foreigners because this is a suitable destination for the development of wine tourism.
- The area of the winery Petrović is 2.5 hectares of vineyards,
- Annually produces 50,000 L of wine, šira, grape juice, spirits, grape brandy Lozovača, grape marc Komovica, liqueur....
- 30% of white and 70% of black wine is produced.
- It is exported to Serbia, Montenegro and the Republika Srpska.
- There is a problem with the border, (excise, VAT with double taxation).
- Spirit (rakija) is harder to export than wine
- The export is mostly done in plastic bottles.

According to the manufacturers’ experience – 15,000 Euros is necessary for a hectare of vineyards and another 20,000 euros for a wine cellar, pressing machines, crushers and other equipment.

Winery vinica- the church of Sveti Stefan

Field conditions

The Kosovo government gives 1000 euros per hectare of vineyards annually, while the Serbian government has given loans with incentives and donations in presses, crushers, vats, etc. For now, no incentives have been made for wine production and export, and it should be done, especially in these circumstances where our people live.

Checking the Importance of Various Factors in Purchasing and Selection of Wine

In the previous Fig. 6, it can be clearly seen that the users are paying great attention to the previous experience, the type of wine, the vintage, the brand, while the shape and volume of the bottle and the shop staff are factors that the examined users do not consider decisive when choosing and buying bottles of wine.

All the analyzed wineries gave a much greater emphasis to technical and technological development during the business expansion period, which was not followed by the appropriate marketing activity in order to win and better positioning in the market.

The impression is that this segment was left to the stigma and inertia of the development of the entire sector, which was especially evident in terms of difficulty in the placement, increasing inventory and billing issues.

Previous research has shown that enterprises can increase their marketing activities through Internet advertising without big additional costs and thus mitigate the negative specificities of the living and business environment in Kosovo and Metohija. Based on the SWOT analysis, it can be concluded that even if there are certain weaknesses and threats to the wine production in Kosovo and Metohija, they can gradually be overcome by harnessing opportunities and chances. In this respect, they should also be put

together on the market and use Internet advertising, which, given the specific business conditions, can significantly assist in the placement and sale of wines

Swot Analysis

<i>Strengths</i>	<i>Weaknesses</i>
● Continuously high quality wine quality ● Long tradition of production ● Modern wine facilities and equipment ● High representation of young vineyard seedlings ● Using modern technology ● A wide range of products ● The winemaker belongs to the younger generation of winemakers ● Noteworthy results in wine exhibitions and fairs ● Recognition of the visual identity of the product ● Possibility of independent organization and management of tasting ● Continuous education	● Insufficiently emphasized promotion that is not adapted to the production expansion ● There are no employees who are specialist in marketing and promotion ● Double VAT, double excise, ● Kosovo buyers are blackmailing and the money is paid only in May next year. High selling wine prices ● Insufficient product information ● Product unavailability to potential customers ● Export is done mostly in plastic bottles and glass bottles in small quantities of 20–40 bottles in vans, buses, but not in tanks due to the problems on the road by the Kosovo police, sanitary inspection, etc.
<i>Opportunities</i>	<i>Threats</i>
● Favorable agroecological conditions for the production of quality raw materials ● Development of specific technologies for the production of wines of indigenous grape varieties ● Preservation of the environment and the possibility of ecological production ● Recognition in the domestic market ● Makes it easier to enter foreign markets ● Joining winemakers in the sales segment and the expansion of the direct retail network ● Joint appearance on the market ● Use of the Internet and social networks in promotion of wine	● Capital intensive production and high dependence on the capital market ● Slower turnover (the coefficient of turnover is less than 1) ● Wine prices in catering facilities are not accessible to a wide range of citizens ● Drop in purchasing power, both domestic and foreign markets ● Large producers that have more capital and have a better marketing approach ● International competition with better infrastructure and institutional support

Conclusion

The purpose of this paper is to study the application of new forms of Internet marketing in terms of solving problems of placement of wine of small and medium-sized enterprises, and to investigate and determine the attitude of users in Serbia towards Internet advertising. Nowadays, the survival of a company directly depends on advertising on the web because in this way potential customers can notice them and to get acquainted with their offer at the moment when the company needs it.

People are looking for information about products or services on the Internet, and therefore it is extremely important for small businesses to be present on the Internet.

There should be no sudden change in advertising. Gradually and in small steps, you get the proper ads and the right customers at a reasonable price. The results of the study suggest that European wine production is decreasing and in this way follows the reduction of consumption due to changes in the way of life and the impact of anti-alcohol campaigns. The results of the research in small and medium-sized enterprises in Metohija indicate that the winemakers have huge problems with the placement of wine due to a specific living and business environment, but the owners of the wineries are not fully and sufficiently acquainted with the advantages of the Internet marketing, but also because of poor internet connection they are not able to use these comparative advantages. The results of the survey indicate that online advertising for small enterprises is the most appropriate advertising. It supports a narrowly targeted audience and it has an extremely fast response, which allows continuous, easy adjustment and especially low cost. That is what is needed for small enterprises. Online advertising allows the existence and survival of the rapid growth of the company, and compared with the payment of sales promoters, or preparation and execution of the campaigns, it is far cheaper, faster and more accurate way to target customers.

The greatest potential and challenge for the placement of wines are social media, especially the social network Facebook. What is obvious is that traders will face more competition in the wine market, as wine production from around the world is expected to increase, as well as the introduction of a set of laws on the prevention of alcohol abuse. This gives extra weight to this kind of research among producers and consumers and contributes significantly to increasing enterprise performance and customer satisfaction.

The fact is that society has just passed the threshold of digital transformation and, in this direction before companies in Serbia are new challenges. In the future inexorably comes to linking new technologies and new tools, such as connecting the coffee machines and washing machines to the Internet. There is the period in which advertising will almost completely take care of a multitude of computer algorithms. Internationalization allows us to reach a larger reach and to create a larger market, where online advertising of many audiences is achieved.

In the analysis of users' attitudes towards internet advertising, presented research results in the world generally differ. Some studies have shown that users have a positive attitude towards internet advertising (e.g., Ducoffe, 1996; Previte, 1999), while others show negative attitudes (e.g., Li *et al.*, 2002; Rettie *et al.*, 2003). Most of the research (e.g., Ducoffe, 1996; Brackett and Carr, 2001; Burns, 2003) as the most important factors that will influence the formation of the point of view about Internet advertising or towards the formation of a view on online ads, emphasizes three factors, which are informativity, entertainment and aggressiveness.

Interactivity and credibility factors were also mentioned (e.g., Brackett and Carr, 2001; Wang *et al.*, 2009). Burns (2003) showed in his study that users have different attitudes towards different forms of online advertising. In other words, some forms of online ads are more attractive to users than others. Online advertising is an opportunity that is available to every Internet user for the development of a web browser, but that does not mean that every online advertising user is competitive. It is therefore important to distinguish the benefits and to identify the weaknesses of online advertising business and to take into account its benefits.

Knowledge of certain forms of online advertising affects the viewpoint of users on this form of advertisement. Advertising should attract the attention of the target audience and fulfill the planned objectives. If we want to be contacted by customers, we must be ready for a quick response and quality expert support, advice, things that can be directed, and in the end to solve problems. Users have a more positive attitude towards advanced forms of online ads than on others. Burns (2003) found that users perceived more advanced forms of advertising as entertaining, but at the same time- disturbing. For example, floating ads have proven to be the most fun but also the most annoying form of advertising. The research results show that video ads are the most popular among users in the region. In Serbia, the largest share of advertising costs is still entrusted to television, which is unsustainable for most small enterprises. Therefore, small enterprises are increasingly relying on online pay-per-click advertising, which provides small initial investment and a gradual increase in advertising costs. This is especially important because companies have programs that are strictly focused, because it is absurd to direct ads to the masses.

Large media such as television, radio and print media are not profitable for the company. In this way, you target thousands of clients for just a few responses and you pay are paying too much for that. This can be afforded by large companies that offer consumer goods and well-known brands. On the contrary, online advertising allows low initial costs with narrow targeting to enable us to maintain financial sustainability. Small businesses generally deal with small margins and a limited sales volume, which requires thoughtful consumption for marketing purposes. This can be afforded by large companies which offer consumer goods and well-known brands. In contrast, online advertising allows low initial costs with narrow targeting to enable us to maintain financial sustainability. Small enterprises generally deal with small margins and a limited sales volume, which requires thoughtful consumption for marketing purposes.

Trends in Europe show growth in video advertising. Researchers predict the continued growth of mobile advertising and advertising via social networks. These are advertising potentials. Understanding the success factors of online advertising for entrepreneurs can be of great help if they are aware of the potential effects of individual factors and how to use them.

This is a period in which, according to the forecasts of the research company Gartner, the director of marketing, will invest more in IT, a period in which ICT can not replace marketing experts, but they will have to acquire new skills and to adapt existing business models and to improve IT cooperation. The impact of ICT on marketing communications will be visible, and from year to year, it will be greater. Based on current experience and research, it can be said that online advertising, in combination with personal communication, has been best shown so far because they are complemented very much.

Therefore, it can be concluded that customers can be met via the Internet and confirm our bid, and companies must strive to be at the right time in the right place and offer them what they need, quickly and efficiently, for mutual satisfaction. Although it is difficult for owners of small and medium-sized enterprises in Metohija region to use these sophisticated technologies and advertising tools, it is necessary to include principles and methods of internet marketing in order to solve the problem of placing and selling wine.

Introduction

Demand and consumption of energy have been increasing drastically due to increasing population, industrial sectors, high-rise commercial buildings, and school buildings. In recent years, Brunei has seen a huge increase in school buildings, where most of these buildings are two stories tall and spaciouly built. Due to this type of building structure, the classrooms and common areas tend to consume significant electrical energy, and this requires architects and civil engineers to revisit the design plan of these buildings to ensure reduced energy consumption. With the aim to assist in efficient building design, monitoring and operation, the relatively new concept of net zero efficient building (ZEB) is getting good attention in the research domain [1]. Energy efficient buildings are often rated better than conventionally designed buildings in indoor climate [2]. Sunikka-Blank and Galvin [3] have investigated energy performance ratings around 3400 German homes. In this research, they found that the occupants consumed, on average, 30% less heating energy than the calculated rating. Marszal *et al.* [4] presented some review-results to facilitate the development of a consistent ZEB definition and a robust energy calculation methodology.

The experience of incorporating energy efficiency, after Hurricanes Katrina and Rita, in four new schools in New Orleans has been discussed in Ref. [5] to help other school districts and design teams with their in-progress and future school building projects in hot-humid climates. The use of Chromogenic in “smart” windows to modify the incoming visible light and solar energy in buildings as well as for other see-through applications has been discussed in Ref. [6], where it has been concluded that the electrochromic (EC) windows seem to be ready for large-scale applications to provide energy efficiency and indoor comfort.

Palmero-Marrero and Oliveira [7] have conducted a general study of the effect of louver shading devices under different climatic conditions, and with the aid of software simulations demonstrated that the use of louver shading devices in the buildings led to comfortable thermal conditions in indoor environment, and might lead to significant energy savings in comparison with the buildings without shading devices.

Zinzi [8] has conducted a study on residential and nonresidential standard building models using cool roof technology. The results demonstrated the potential of this technology to improve the energy performance of Mediterranean residential buildings. Using their analytical model, Wang *et al.* [9] demonstrated that the classroom energy-demands for ventilation and cooling systems could be reduced with the promotion of heat recovery efficiency of the ventilation facility, and in this case, the energy conservation ratio of the air-conditioning unit would decrease with an increase in the temperature of the supplying air.

Santamouris *et al.* [10] dealt with the experimental investigation and analysis of the energy and environmental performance of a green roof system installed in a nursery school building in Athens. The energy performance evaluation showed a significant reduction of the building's cooling load during summer. Moreover, the influence of the green roof system in the building's heating load was found to be insignificant.

Chidiac *et al.* [11] have applied energy retrofit measures (ERMs) to reduce the energy consumption of buildings. They found that heating and cooling loads vary with climate and building characteristics, and react differently to some ERMs. Huang and Niu [12] have studied a superinsulating glazing system, which was formed by two layers of conventional single clear glass panes and a layer of silica aerogel filled in between. Several glazing samples were prepared. The thermal and optical parameters were measured. An annual heating, ventilation, and air-conditioning (HVAC) system energy analysis was also conducted based on the space cooling load simulation. The result indicated that in humid subtropical climates like Hong Kong, the application of silica aerogel glazing system can reduce the annual space cooling load by around 4% in a typical commercial building. They also found that the reduction in envelope heat gain could be around 60%.

Jin *et al.* [13] developed a prototype of phase change material thermal shield (PCMTS) and evaluated its thermal performance in three different locations within the cavity of a typical North American residential wall system using a dynamic wall simulator. The experimental results showed that, compared to a wall without a PCMTS, the peak heat fluxes were reduced by as much as 11%.

In Ref. [14], the authors carried out a survey to gather data that were related to energy consumption in school buildings. The results of this survey were documented in the most diverse fields and units: global energy consumption values, electrical energy consumption, fuel consumption for heating, energy data consumption of schools expressed in annual cost per unit of heated/cooled surface area ($\$/\text{m}^2$) or per unit of heated/cooled volume ($\$/\text{m}^3$) or, finally, as the annual cost per student ($\$/\text{student}$).

Xing *et al.* [15] presented an analysis of energy consumption in 270 schools located in the city of Tianjin, China. The analysis focused specifically on calculating the space heating energy consumption indexes and non-heating energy consumption indexes of different types of schools, aiming at providing reliable and precise data for the government to elaborate policies and measures.

A flexible wireless measurement system for the temperature monitoring of a school building has been proposed in Ref. [16]. Airaksinen [17] studied different schools and day-care centres in southern Finland in terms of their primary energy usage. Here, the author investigated the influence of the design and construction phase to the overall energy performance of the buildings compared to similar existing buildings.

Based on the review works, some alternative glass materials are considered for improving the overall efficiency of the school buildings. As glass materials, Graylite II and Solarcool provide a lower solar heat transmission coefficient and protect the interior including materials, clothes, and their colors from fading by blocking 94% of the sun's ultraviolet energy [18].

In this article, the energy usage by the air-conditioning, lighting, and ventilation systems at two secondary schools in Brunei Darussalam has been investigated, and the results are compared with the standard data sets. In addition, two types of monolithic glass materials have been proposed for windowpanes with the aim to optimize the electrical energy usage.

Climate in Brunei Darussalam

The country Brunei Darussalam is located 4 degrees north of the Equator. Due to this location, the weather is persistently hot and humid as shown in Table 1. The average temperature varies little year to year. The average temperature was found to be 27.6, 28.3, and 26.8°C for the years 2012, 2013, 2014, respectively. The wind direction is generally from south to south west. Since Brunei Darussalam is located near the Equator, the solar radiation remains more or less constant as can be seen in Table 1.

Data Collection

Building Physical Data

The two schools, SA and SB, were selected from the Sengkurong subdivision of Brunei-Muara district of Brunei Darussalam. These two schools are not connected to the local renewable energy system network. Most of the schools have more than two buildings, which consist of the administrative block, multipurpose hall, prayer hall, academic block, and science block. From architectural plans, the data, such as the orientation of buildings, floor space, and wall and window areas, can be found, and the type of materials used for construction can also be obtained. The floor space area used in SB is bigger than SA, and the spaces between the buildings are also roomy. Whereas, SA is confined to a much smaller expanse when compared to SB. Two types of windows along with glass materials are shown in Figs. 1 and 2.

Table 1 Average climatic data

Year	Wind speed (m/s)	Wind direction	Temperature (°C)	Solar radiation W(Kw/m ²)	RH (%)
2012	2.52	South and south west	27.6	5.16	81.3
2013	2.54		28.3	5.17	81.6
2014	2.48		26.8	5.15	81.4

Methodology

Proportion of Energy Used in Schools

The estimated energy consumption can be calculated using the following formula:

$$E_c = \frac{P_r}{P_t} \times \text{AEC} \quad (1)$$

Cooling Load Estimation

The building orientation, weather condition, building spacing, and building materials need to be known to estimate the cooling load of any building. Brunei Darussalam has an equatorial climate characterized by a uniform high temperature, high humidity, and heavy rainfall. Temperatures range from 23 to 32°C, while rainfall varies from 2500 mm annually on the coast to 7500 mm in the interior.

To cool down a room space it is required to remove heat from three main sources. The heat generated by these three sources are, namely, heat gain through wall and roof, solar radiation through windows, and heat generated by the occupants. The heat gains through walls or roofs are assumed to be under steady-state conditions and the heat gain can be calculated as,

$$Q_{w/r} = U_{w/r} A_{w/r} (t_o - t_r) \quad (2)$$

The room air temperature at the air-conditioned space and fans are found to be 25 and 29.1°C, respectively. The outside temperature is found to be 31°C. According to design, the thicknesses of the wall for SA and SB are found to be 120 and 125 mm, respectively. The U-value of the brick wall for both schools is assumed to be 2 W/m²K. The surface area of the wall is calculated after deducting the area occupied by the windows.

The heat gain through windows can be calculated as,

$$Q_{\text{window}} = I \times F_t \times A_g \quad (3)$$

The heat gain from occupancy or people is calculated by the following equations:

Sensible heat gain from occupants is

$$Q_s = q_{s,\text{person}} \times N \quad (4)$$

Latent heat gain from occupants is

$$Q_L = q_{L, \text{person}} \times N \quad (5)$$

Heat gains by natural infiltration may be calculated using the following equations:

$$Q_{si} = 0.33nV(t_o - t_r) \quad (6)$$

$$Q_{Li} = 0.8nV(g_o - g_r) \quad (7)$$

The air moisture content in this equation can be obtained from the psychrometric chart by connecting the wet bulb and dry bulb temperature of the room air and the outside air on the chart to find the specific humidity. The values of the wet and dry bulb temperatures can be obtained from the psychrometer.

To take a reading, the instrument is opened by withdrawing the inner frame from the case. Then it is thoroughly wet by placing the exposed end under cold running water for about 30 s. To take a reading, the psychrometer handle is held vertically and is rotated for about 60 s at a rate of two to three revolutions per second. After the revolution is completed, the wet and dry bulb temperatures are noted.

Consumption per Meter Square and per Person

By calculating energy consumption per meter square and per person, the amount of energy consumption used by air-conditioning, ventilation, and lighting systems for floor space area and per person can be found. These data values help to determine whether the schools use the right amount of energy or more energy. These energy values are calculated using the following equations:

$$E_m = \frac{E_c}{A_f} \quad (8)$$

$$E_p = \frac{E_c}{NP} \quad (9)$$

Results and Discussion

The total consumption of electrical energy used is split into three major divisions. These are air-conditioning, lighting, and ventilation. The air-conditioning system in a building will certainly reduce the effect of heat and produce comfortable dry air. The rate of direct sunlight penetration can be reduced through good orientation of the school building. The intensity of the light entering the building will affect the rate of energy consumption of the building. With no wind movement, the heat will accumulate in the building, thus the heat gains will be more. The percentages of energy used by air-conditioning, lighting, and ventilation (fan) components in SA and SB are shown in Figs. 3 and 4, respectively (from Eqs. (2)–(7)). From Figs. 3 and 4, it is observed that the major contributor of energy consumption is the air-conditioning system. The percentages of energy used by the air-conditioning system are 83 and 93% for SA and SB, respectively.

This is because of the short façades of SA, facing east and west, which enabled less entry of direct sunlight compared to SB. Moreover, since different buildings of SA are in close proximity to each other, direct sunlight rays are mostly blocked by the adjacent buildings, which in turn reduces heat entry to a number of rooms of the buildings in SA. Also, the total sun-facing surface area of the wall, window, and roof for the entire building for SB is greater than SA. It means the heat gains by SB through the wall, window, and roof is greater than SA. Since the air-conditioning system consumes the major portion of the total consumed energy, it is therefore important to look into the operation and maintenance schedule of this system carefully to achieve better efficiency.

Using Eqs. (2)–(7), the cooling load requirement for SA and SB are found to be 773.35 and 1337.25 kW, respectively.

The reserve factor for the cooling system can be calculated as,

$$F_{rc} = \frac{P_t}{P_d} \quad (10)$$

From the cooling load calculation, it is found that the reserve factor for cooling for SA and SB are 1.08 and 1.77, respectively. It means that the reserve factor for SA is reasonable. For SB, the calculated value is found to be very high. From this calculation, it is found that most of the cooling equipment in SB is unutilized. This anomaly needs to be investigated further.

The air-conditioning (AC) power consumption data gathered from SA and SB are compared with similar data collected from schools in Canada (SC) and Ireland (SI), as shown in Fig. 5. The AC power consumption in SA is comparable with SC and SI, whereas, this consumption in SB is much higher than SC and SI as can be seen in Fig. 5. This condition can be explained as follows.

Most of the long façades of the buildings in SA are facing east and west, whereas, the long façades of SB are facing toward north and south. The right orientation for long façades of the building is to face toward east and west. The operation hours of the schools are from 8 am to 4 pm. The average cooling load factors for that time for a building with an orientation with east, west, north, and south are 0.41, 0.34, 0.57, and 0.81, respectively. In view of the above, the cooling load factors for SA are lower than SB. Also, as SB is more spacious, it is possible that the infiltration losses are more in SB when compared to SA. As such, from the above

Fig. 3 Energy consumption in school A (SA).

Fig. 4 Energy consumption in school B (SB).

explanation, it is obvious that SA should have a lower AC power consumption than SB. The major contribution toward the heat gain is through the roofs, windows, and the walls of the buildings. The percentage of area for the windows of SA and SB are calculated from Table 5 as,

$$SA = \frac{139.08}{1656.58} \times 100 = 8.40\%$$

$$SB = \frac{427.28}{3270.03} \times 100 = 13.07\%$$

Whereas, with standard glass windows, the percentage of heat gain through the window for SA and SB are calculated from Tables 6 and 7 as,

$$SA_{Normal} = \frac{29532.2}{57725.6} \times 100 = 51.16\%$$

Fig. 5 Comparison of air-conditioning (AC) power consumption in different countries.

Table 8 Energy usages with new glass materials

Glass type (1/4")	Transmission factor	SA (%)	SB (%)
Graylite II	0.08	15.13	24.42
Solarcool	0.04	12.10	13.91

$$SB_{Normal} = \frac{90772.56}{138556.1} \times 100 = 65.51\%$$

Therefore, close attention in choosing the window materials is required for optimizing electrical energy usage. The heat energy gain through the window was calculated using standard windowpanes with a transmission factor of 0.47. In this case, there is a need to search for a glass material with a low transmission factor. Two types of glass materials, namely, Graylite II (1/4") and Solarcool (1/4") [18], with their lower transmission factors are used to optimize the energy usage whose basic characteristics have been outlined below [18].

Graylite II [18] is an uncoated glass with a very low solar heat gain coefficient. It provides ideal brightness control and privacy glazing with visible light transmittance of 12%. This type of glass can be heat-strengthened, tempered, and laminated and is readily available as a standard product. It delivers optimum levels of solar control together with a fashionable, nearly black appearance.

Solarcool glass [18] has been a popular choice for commercial structures because of its cool, light-gray appearance and ability to control solar heat gain and glare. This type of glass may also be combined with other types of glasses to improve the solar heat gain performance and lower U-values. It has light-gray color, which makes it an attractive choice in combination with almost any other exterior cladding material. The properties of Graylite II and Solarcool glasses are mentioned in Table 8 [19,20].

Both of the aforementioned glasses might contain calcium fluoride (CaF₂) and Suprasil (fused silica), which can reduce the ultraviolet ray and physical light transmission significantly.

The heat gain through the windows of SA using Graylite II and Solarcool can be obtained as,

$$Q_{window} = I \sin \alpha \times t_f \times A_{wi} = 493 \sin (66.4) \times 0.08 \times 139.09 = 5026.94 \text{ W}$$

$$Q_{window} = I \sin \alpha \times t_f \times A_{wi} = 493 \sin (66.4) \times 0.04 \times 139.09 = 2513.47 \text{ W}$$

The heat gain through the windows of SB using Graylite II and Solarcool can be obtained as,

$$Q_{window} = I \sin \alpha \times t_f \times A_{wi} = 493 \sin (66.4) \times 0.08 \times 427.28 = 15442.58 \text{ W}$$

$$Q_{window} = I \sin \alpha \times t_f \times A_{wi} = 493 \sin (66.4) \times 0.04 \times 427.28 = 7721.29 \text{ W}$$

The percentage of heat gain through the window for SA with Graylite II and Solarcool can be calculated from Table 6 as,

$$SA_{Graylite II} = \frac{5026.94}{33220.34} \times 100 = 15.13\%$$

$$SA_{Solarcool} = \frac{3716.56}{30706.87} \times 100 = 12.10\%$$

While the percentage of heat gain through the window for SB with Graylite II and Solarcool can be calculated from Table 7 as,

$$SB_{Graylite II} = \frac{15442.58}{63220.34} \times 100 = 24.42\%$$

$$SB_{Solarcool} = \frac{7721.29}{55504.80} \times 100 = 13.91\%$$

The above percentage of heat gain values have been recorded in Table 8.

The intensity of illumination for SA and SB is found to be 720 and 1005.75 lux, respectively. However, according to standard, the intensity of illumination recommended in workspaces is around 250–500 lux/m². Comparing the calculated results with the standard values, it is found that both schools illuminate the workplace using more than the required standard value. This energy wastage in illuminating the school spaces results in a negative impact on the overall energy efficiency of both schools.

The energy usage in ventilation per person for SA and SB is found to be 5.5 and 38.25 W, respectively. According to ASHRAE 62.2 [21], the ventilation requirement is 7 L/s per person. Using standard air pressure of 1 kPa and density of 1.2 kg/m³, the fan power is calculated to be around 7 W. After comparison, it is found that SA uses close to the required calculated power for ventilation, whereas, SB uses 5.5 times more than the required power. Since the air-conditioning system consumes the majority of the energy, it is necessary to look into its operation, maintenance schedule, and user awareness to achieve better efficiency.

A survey comprising 12 questions on energy efficiency and awareness on usage was conducted among the teachers and students of SA and SB. The result from this survey has shown that the majority of the participants agree that energy saving is important. The results also show that the majority of the participants switch off their appliances when they are not in use. However, the majority of the participants reportedly switched off their air-conditioning system only occasionally during the rainy weather when the temperature of the air is usually low. According to the survey, 80% of passage lights including toilets, corridors, etc. were seen to be

Table 9 Properties of Graylite II and Solarcool glass materials

	<i>Transmission factor</i>	<i>Heat gain coefficient</i>	<i>Shading coefficient</i>	<i>Outdoor visible light reflectance</i>	<i>U-value summer</i>
Graylite II	0.08	0.34	0.25	0.04	0.50
Solarcool	0.04	0.58	0.67	0.14	0.50

turned off in SA, whereas that number was found to be 58% for SB. The average power consumptions for SA and SB were found to be 10,338.89 and 126,380 kWh, respectively. The calculated standard deviations for those schools were 106.375 and 1491.458 kWh, respectively. The standard deviations were 1 and 0.1% of the average energy consumptions for SA and SB, respectively. This means that the 95% energy consumption is within a ± 2 and $\pm 0.2\%$ range for SA and SB, respectively. Since the weather conditions in Brunei vary very little throughout the year (see Table 1), it is expected that the variation of electricity consumption over the year will be within a narrow range, which is evident from the aforementioned numbers. The values of the median and the mode for the energy consumptions for both schools were found to be equal. It means that the overall power consumption for both schools is *normally* distributed (Table 9).

Conclusions

Two secondary schools, SA and SB, were considered for investigating the electrical energy usage. It is found that the air-conditioning system consumes the most energy, amounting to 83 and 93% of energy for SA and SB, respectively. Comparing with SA, SC, and SI, it is concluded that SB is using significant power in its air-conditioning system due to its physical orientation. Although the percentage of areas of windows are smaller (8.40 and 13.07% for SA and SB) compared to the other contributing items in the energy consumption, the windows were found to be the major contributing factors toward the air-conditioning load, which was 51.16 and 65.51%, respectively. It has been found that the percentage of electrical energy usage can significantly be reduced to 15.13 and 24.42% using Graylite II for SA and SB, respectively, while these numbers can further be reduced to 12.10 and 13.91%, respectively, with the use of Solarcool glass material. The illumination of the schools is found to be higher compared to the standard values. In addition, it is suggested that a provision can be made to allow sunlight to enter the building through smart electronic glazing, which will further reduce the power used to illuminate both the schools. The energy usage for ventilation in SA is close to the standard value where it is 5.5 times more in SB. The higher energy usage in SB due to ventilation requirements has to be further investigated. Survey results on energy usage show that there is less awareness in the use of lights in the less frequently used areas such as passages, toilets, etc. From the statistical analysis, it is found that the energy consumption for both schools follows the normal distribution.

Acknowledgments

An Overview of the Global Ship Recycling Industry

Kanu P Jain and Jeroen Pruyn, Delft University of Technology, Delft, The Netherlands

© 2017 Elsevier Inc. All rights reserved.

Introduction

This article presents an overview of the ship recycling industry and the relevant international regulations governing the recycling of end-of-life (EOL) ships. The industry overview is presented by providing insight into three Ws – when, why, and where ship recycling is carried out. This article also provides an insight into the methods used for recycling, transaction terms and conditions, and the historic volumes of EOL ships globally. This discussion is followed by an extensive overview of the material composition of EOL ships. The regulatory overview is presented by discussing the provisions of the Basel Convention, the Hong Kong Convention (HKC), and European Union (EU) ship recycling regulation. The final section of the article explains what green ship recycling is and what criteria, based on the international regulations, can be used to identify a green ship recycling yard.

Industry Overview

When and Why Are Ships Recycled?

The answer to why ship recycling is carried out is rightly put by [Stopford \(2009\)](#) as “scrapping will occur only when the industry’s reserves of cash and optimism have been run down.” Ship recycling is carried out to remove inefficient ships from the market, which in turn generates cash flow for ship owners and tackles oversupply of ships in the freight market. Ship recycling, besides being a business decision for the ship owners, is also necessary for the continued renewal of the shipping fleet. Naturally, the oldest ships are removed first due to their high maintenance costs.

A large-scale scrapping of ships is carried out only when the entire shipping industry does not anticipate any prospects of employing ships profitably in the foreseeable future or when the companies need cash urgently ([Stopford, 2009](#)). According to [Buxton \(1991\)](#), scrapping is the most attractive option for the ship owners when the prospects of anticipated profitability of a ship are poor and the second-hand prices are correspondingly low. If the market is expected to improve before the technical life of the vessels ends, they are usually laid-up in anchorage outside a port instead of recycled.

The decision to recycle a ship is based on the following factors ([Buxton, 1991](#); [Stopford, 2009](#)):

1. obsolescence,
2. current earnings,
3. future market expectations, and
4. scrap prices.

These factors regulate the demand and supply dynamics of both the ship recycling market and the freight market because most ships that are taken out of the freight market are supplied to the ship recycling market. In one way or the other, these factors affect the finances of a shipping company as explained in the subsequent sections.

Obsolescence of ships

Obsolescence of a ship depends on several factors including physical, technical, and regulatory. Therefore, a wide range of ages of the ships sent for recycling can be observed in the datasets recorded for ship recycling. For example, [Buxton \(1991\)](#) observed a minimum age of 8 years and a maximum age of 80 years for the 248 ships scrapped in 1984. The average age of the ships sent for scrapping is generally considered to be about 25–30 years ([Kagkarakis et al., 2016](#)). However, [Knapp et al. \(2008\)](#) determined the average age of ships at which they are recycled as 22 years, based on a dataset of ships over 100 gross tonnage (GT) recycled over a period of 7 years from 2000 to 2007.

Physical obsolescence

The physical deterioration of ships due to aging is a natural process that takes place gradually. As the ship grows old, wear and tear of its hull and machinery increases. Therefore, the ship owners are required to spend an increased amount of money on the routine repair and maintenance of the older ships, making them costlier to operate. The repair and maintenance costs are high especially during the fourth and fifth special surveys of the ships. The special surveys are carried out every 5th year of operation for renewing the class certificate of the ship. It includes in and out-of-water inspection of the ship’s hull to verify its structural integrity and conformance of ship’s systems, machinery, and equipment with the applicable class rules ([IACS, 2011](#)). This docking is usually expensive both in costs and foregone income. The phenomenon of deterioration of a ship’s hull and/or machinery to such an extent that it becomes unworthy of repair is called as physical obsolescence ([Buxton, 1991](#)).

Technical obsolescence

The technical obsolescence is indicated by a ship, which, despite being physically sound, is no longer profitable to remain in service due to increased competitiveness by a more efficient ship type. As a result, such ships are likely to be scrapped. For example, three Batillus class VLCCs (550,000 T deadweight) were scrapped in the mid-1980s at the age of 7–10 years due to the lack of route and trade flexibility available in the smaller vessels, amidst the reduction of parcel sizes well below their maximum capacities due to the fragmentation of crude oil supplies (Buxton, 1991). Similarly, the tankers powered by inefficient steam turbines were gradually replaced by the ships powered by fuel-efficient diesel engines by the 1980s (Buxton, 1991; Stopford, 2009). Some ship owners of container ships even resorted to retrofit the 1970s built container ships with the diesel engines to replace the steam turbines (Evans, 1989). The scrapping of multideckers in the late 1960s due to the containerization is also an eminent example of technical obsolescence (Stopford, 2009).

Regulatory obsolescence

The scrapping of ships due to regulatory requirements can be defined as regulatory obsolescence. For example, a phase-out schedule for single-hull tankers entered into force in 2005 as amendments to Annex 1 of the MARPOL convention (IMO, 2016). It was enforced after a series of accidents involving tankers leading to massive oil spills resulting in irreparable environmental damage, to reduce the risk of oil spills from tankers involved in low energy collisions or groundings. It required the tankers of single-hull construction to phase out or convert to a double hull by a proposed deadline based on their year of delivery. The schedule decided by the International Maritime Organization (IMO) ensured that all single-hull tankers were phased out by the end of 2010.

Port state controls, vetting inspections, statutory surveys, etc. are other such regulatory issues that affect the supply of ships in the demolition market. These issues force ship owners to decide on whether to invest in the maintenance and continue operating a ship or to sell it either for scrapping or in the second-hand market (EC, 2004).

Current earnings and market expectations

Beside the above mentioned clear indicators of low earnings, the market itself can also be depressed. Therefore, the current earnings and future market expectations are two important factors, based on which ship owners decide whether or not to continue trading a vessel in the shipping market. The low earnings either due to high operating costs or due to low freight rates cause a decline in the profitability of running a vessel. This dictates that a ship owner put certain cost-cutting measures in place; for example, slow steaming, laying up ships for a certain period of time, converting ships to suit alternative trades, etc. After exhausting all cost-cutting measures, a ship owner is left with two main options: one, continue to operate in the market incurring losses, expecting freight rates to improve in the near future; and two, sell either in the second-hand market for continued trading by another owner or in the ship recycling market for dismantling and recycling (Buxton, 1991).

A ship owner's decision to continue operating the unprofitable ship during a recession, based on his expectations of higher freight rates in future may be justified because the earnings during a freight rate boom are so great that they can overcome the loss incurred by operating in the market experiencing a slump in freight rates (Stopford, 2009). The ship owner's expectations of lower freight rates for a long period of time may force him to sell his ship. The decision to select the recycling market over the second-hand market to sell a ship is based on its selling ability and market value in the second-hand market. When either the scrap value is more than the market value or there is no buyer in the second-hand market, the ship is likely to be sold in the recycling market (Stopford, 2009).

A low freight rate scenario can be seen during the times of high supply and low demand of ships for transportation. A larger supply of ships than is required by the market always creates pressure on the freight rates. The continued imbalance between the demand and supply of ships brings the freight rates down to such low levels that ship owners cannot operate their ships profitably and resort to scrapping the old ships. This was recently observed in the dry bulk market. During the period from November 2014 to June 2015, Baltic Dry Index (BDI), representing the bulk freight rates, declined continuously from the levels of 1450 to about 580 (Fig. 1), which led to a record ship breaking activity of 10.9 million deadweight tonnes in the second quarter of 2015 (Clarksons, 2016). Similarly, continued depressed levels of BDI from a high of 1200 in August 2015 to a low of 290 in February 2016 (Fig. 1) led to an extensive ship demolition of about 10.1 million deadweight tonnes in the first 3 months of 2016 (Clarksons, 2016). The continued demolition of bulk carriers in 2015 and 2016 led to a reduction in the average scrapping age for bulk carriers from 33 years in 2007 to 24 years so far in 2016 (Clarksons, 2016).

The scenario of the large-scale scrapping of ships can be seen during the times of recession when the economic growth rate is low. In such a scenario, the demand of ships for maritime transportation is low because it is a derived demand and depends largely on the amount of cargo required to be transported, which is affected by the economic growth rate. This means that during a low gross domestic product (GDP) growth rate, a lesser amount of cargo is available for transportation. Therefore, a lower number of ships are required. In such a scenario, more and more ships are available for recycling due to an imbalance created between the demand and the supply of the ships for transportation. This is clear from Fig. 2, which depicts the number of ships recycled every year from 2002 to 2014 superimposed with the GDP growth rates of various countries and the world. The most notable point on the graph (Fig. 2) is 2009 when the world GDP growth rate was negative and the number of ships recycled touched the 1600 mark, which was a record at that time. This record was later surpassed in 2012 due to continued low levels of freight rates and GDP growth rates across the ship types and the countries, respectively. The high amount of ship recycling activity seen in 2009 is partly attributed to the regulatory obsolescence.

Scrap prices

Scrap prices do not play a very important role in the ship owner's decision on when to scrap a vessel as much as in a decision on where to scrap a vessel (EC, 2004). The most important driver, as discussed before, is the operational cost of a vessel at the given level of the freight rates. A ship operating unprofitably with no expectation to be profitable in the near future is likely to end up in a ship recycling yard for scrapping even at a low scrap price. However, the decision to scrap a ship can be delayed slightly if an

increase in the scrap prices is anticipated in the short term. A ship recycling yard offering a high price for buying an EOL ship is always attractive to the ship owners. The offer price of an EOL ship depends on several global, local, and other factors.

The most basic economic concepts of supply and demand form the *global factors* affecting the offer price of EOL ships. In the ship demolition market, the supply of obsolete ships is influenced by the decision of ship owners to scrap their ships, whereas the demand is mainly influenced by the demand for scrap steel in the steel-making industry (Kagkarakis *et al.*, 2016; Sujaudhin *et al.*, 2016). The high supply of obsolete ships in the demolition market coupled with a low demand for scrap steel lowers the offer price, while a low supply of ships during a high demand for scrap steel results in a high offer price (Jain *et al.*, 2016). However, there is a limit to which the offer price responds to the supply and demand forces of the ship demolition market because the demand for EOL ships is an indirect demand that is created due to the demand for scrap steel in the steel-making industry.

The global ship recycling yards are just one source of scrap steel, and contribute only about 1.5% of the global needs of the steel-making industry for scrap steel (Mikelis, 2013b). The demand for scrap steel is also fulfilled by other sources, such as EOL vehicles, construction waste, other obsolete products, and scrap generated at steel mills and factories producing finished goods. Therefore, other markets influence the price of scrap steel much more than the amount of ships offered for recycling mainly due to their relatively small quantity. Hence, the offer price to buy an EOL ship is dictated by the price of scrap steel rather than the demand and supply dynamics of the ship demolition market, as also demonstrated by Kagkarakis *et al.* (2016) in a research on forecasting the scrap price of EOL ships.

The local factors influencing the offer price of EOL ships include health, safety, and environmental standards of a ship recycling yard, end use of scrap steel (melting or rerolling), demand for other recyclable items (nonferrous scrap, used machinery, furniture, etc.) in the market, labor wages, waste disposal costs, taxes, and recycling method employed (beaching, slipway, alongside, drydock) (EC, 2004; Jain *et al.*, 2016; Sarraf, 2010).

The other factors affecting the offer price are distance from the last port of call of the ship and the recycling yard, contractual terms and conditions, such as “on delivery” and “as-is, where-is,” hull configuration in terms of complexity, ship's compatibility with the recycling yard in terms of size and draft restrictions, and items remaining on board, such as bunkers, waste oil, spares, etc. (Jain *et al.*, 2016).

The current average offer prices (March 2017) as obtained by GMS (2017) are in the range of 320 \$/LDT for the Indian subcontinent, while for China and Turkey they are about 270 \$/LDT and 210 \$/LDT, respectively.

Where Are Ships Recycled and in What Quantity?

The ship recycling industry has historically been a mobile industry. It has witnessed a geographical shift through time in the quest for low labor costs and high regional demand for scrap steel (Kagkarakis *et al.*, 2016).

The industry was initially established in the highly industrialized countries, such as the United Kingdom, United States, and Japan when damaged ships were dismantled after the Second World War (Kagkarakis *et al.*, 2016; Stopford, 2009). Subsequently, it moved to Mediterranean countries, such as Spain and Turkey, due to stringent labor safety rules and environment protection laws (Kagkarakis *et al.*, 2016; Sujaudhin *et al.*, 2015). Japan remained a major player till the early 1990s (SAJ, 2009).

In the 1970s, the ship recycling industry started moving to Asian countries, such as Taiwan, China, and South Korea. By the mid-1980s, when scrapping was very high, the industry in these countries peaked with almost three-quarters of the global ship breaking business acquired by them (Stopford, 2009). Although China and South Korea entered the ship breaking business later than Taiwan (in the early 1980s), they quickly became leading buyers of EOL ships for scrap (by the mid-1980s) (SAJ, 2009).

The decline of industry in South Korea started in the late 1980s (Fig. 3) when the wages rose and the shipbuilding industry expanded. At the same time, as the economy grew and labor costs increased in Taiwan, the industry became unattractive and most yards were closed by the early 1990s. China, on the other hand, continued operating its demolition yards albeit with a steady decline in the market share due to government regulations controlling currency for purchasing ships and environmental regulations (Stopford, 2009). Although its market share fell from 23% in 1986 to 9% in 1995 and 3% in 2005, it remained in the top five in most years to date (SAJ, 2009; Stopford, 2009).

The withdrawal of Taiwan, South Korea, and Japan and the decline of China from the demolition business from the late 1980s to the early 1990s moved the industry gradually toward the Indian subcontinent (Fig. 4). The subcontinent countries, such as India, Pakistan, and Bangladesh, had a negligible market share before the 1980s but they witnessed steady growth through the 1980s and 1990s till today (SAJ, 2016). The ship recycling industry flourished greatly in these countries in the last three to three and a half decades.

The growth trends of the global ship recycling industry show that since 1993, the industry is concentrated mainly in five countries, namely India, Pakistan, Bangladesh, China, and Turkey (Fig. 4). The level of activity in these “top five” countries varies from year to year and depends on the number of ships available for scrapping. They have regularly shared 97–98% of the EOL tonnage for the last 15–20 years (Mikelis, 2013b; SAJ, 2016). However, the fluctuations in market share of these countries are highly prominent. Turkey is the smallest of the top five recycling states in terms of the annual tonnage recycled but it recycled almost equal or more tonnage than the rest of the world in the recent past.

The last 5-year trend of the top five countries versus the rest of the world in terms of percentage of total tonnage (LDT) recycled is shown in Fig. 5. An interesting observation from this figure is that subcontinent countries – India, Pakistan, and Bangladesh have invariably accounted for at least two-thirds of the global ship recycling activity.

Fig. 3 Growth of ship recycling industry from 1976 to 2007 in various countries in terms of million gross tonnage (GT) of ships recycled. Courtesy of SAJ, 2009. Shipbuilding statistics March 2009. The Ship Builders' Association of Japan.

Fig. 4 Growth of ship recycling industry from 1990 to 2014 in various countries in terms of million gross tonnage of ships recycled. Courtesy of SAJ, 2016. Shipbuilding statistics March 2016. The Ship Builders' Association of Japan.

The ship recycling sites in each of the five major countries are clustered in a particular region. The sites in Pakistan are mainly located near Karachi at Gadani Beach situated in Balochistan province, while the sites in Bangladesh are located on the 18-km Sitakunda coastal strip situated north of the port of Chittagong. The Indian recycling sites are located in Alang in the state of Gujarat situated on the west coast, while the Turkish recycling sites are located in Aliaga, a town situated on the Aegean Sea, 60 km

Shipbreaking – Bulletin of information and analysis on end-of-life ships. Available at: <http://www.robindesbois.org/en/a-la-casse-bulletin-dinformation-et-danalyses-sur-les-navires-en-fin-de-vie/>.

north of Izmir port. The ship recycling in China is performed mainly in two locations – yards located along the Yangtze River in North, close to Shanghai and yards located along the Pearl River in South, in Guangdong Province. Some yards are also located close to Tianjin, North of Shanghai.

A small number of shipbreaking companies are also scattered in the United Kingdom, United States, Canada, and European countries, such as Spain, Belgium, The Netherlands, etc. specializing in breaking warships, fishing vessels, and other high value vessels (Abdullah *et al.*, 2013; Kagkarakis *et al.*, 2016; Stopford, 2009) but do not pose any competition to Asian ship breakers due to high labor costs, lack of a ready market for recycled material, and stringent environmental regulations.

The size of a recycling yard is generally determined by its annual dismantling capacity, which varies from one country to another. For example, yard sizes in the Indian subcontinent are in the range of 20,000–150,000 LDT per year. The size of the yards in Turkey is in the range of 50,000–100,000 LDT per year whereas, in China, yard sizes vary from 30,000 LDT to 1.2 million LDT per year (ClassNK, 2017; LR, 2017). In general, the yards operated in Turkey and the Indian subcontinent are small to medium-sized, whereas in China, medium to large-sized yards are operated.

Recycling Methods

Ships are recycled by employing different types of methods in different parts of the world. The methods are similar in most aspects, especially the fact that all ships are cut apart to retrieve materials for recycling, irrespective of the method of recycling employed. The major difference between various methods is the way ships are docked and the level of mechanization used to carry out the recycling process. The difference between various methods depends mainly on the location of the yard and the prevalent practices in the region.

Classification according to the way ships are docked

There are four general methods to dock ships for dismantling, i.e., beaching, slipway, alongside, and drydock.

Beaching

Beaching is the term generally used for dismantling ships at the intertidal zone of a beach (Fig. 6). Ships are run ashore, as far up the beach as possible, at high tide to leave them grounded at low tide (Hougee, 2013). Ships are often unable to travel as far up the beach as desired under their own power and are left stranded on the mudflats. They are then pulled higher onto the beach using chains or heavy steel wires attached to large winches on the beach (LR, 2011). As steel blocks and other equipment of a ship are progressively cut in the intertidal zone using cutting torches, ships become lighter and easy to pull up the beach by winches. Large blocks are often cut from the ship, released onto the mudflats, and dragged individually by the winches onto the shore. Once onshore, everything is cut into smaller pieces as required by end buyers.

The beaching method is used to dismantle about two-thirds of the world's EOL ships, i.e., 66% in terms of GT (Mikelis, 2012) as well as lightweight tonnage (Fig. 5). The main locations include Chittagong in Bangladesh, Alang in India, and Gadani in Pakistan. The large tidal difference and extensive mudflats of these areas are utilized to drive ships up the beach (Lee, 2012). The beach is generally divided into "plots" of about 50 m wide and up to 100 or 150 m deep. A major issue with dismantling ships on tidal mudflats is that any spills of oil or cargo remaining on board are likely to be swept out to sea by the next tide (LR, 2011). However, this can be avoided by taking necessary measures and following the correct procedure.

Brussels: NGO Platform on ship breaking, reprinted with the author's permission.). (b) Pictorial representation of the slipway method. Courtesy of Lee, M.A., 2012. Korean perspectives on ship recycling. MSc Thesis, IIIEE, Lund University.

Slipway

This method is a modification of the beaching method and is also called nontidal beaching (LR, 2011; Mikelis, 2012). The major difference between beaching and the slipway method is that of the tide. It is practiced in areas with a low tidal difference, especially in Turkey (Hougee, 2013). Other than Aliaga in Turkey, slipway recycling is practiced in many small-scale historical recycling locations, such as Inverkeithing in the United Kingdom and other locations in Europe and United States today (LR, 2011). In the United States slipways are generally 400–700 feet long (120–200 m) and 100–120 feet wide (30–36 m) at the entrance (USEPA, 2000). About 4% of the world's recycling capacity uses nontidal beaching method for ship recycling (Mikelis, 2012).

Although, in this method also, the ship is beached either against the shore or, preferably, a concrete slipway extending to the sea, an element of control is available due to the lack of tides. This means that any accidental spillages can reasonably be contained and the lifting and access operation takes place at a predictable and relatively stable waterfront (LR, 2011). Normally, the hull and machinery pieces are removed from the ship by mobile crane working from the shore, as shown in Fig. 7. It is generally acknowledged that the low tidal difference and improved access to the hull and the working area offer advantages for the safe and environmentally sound operations compared to the beaching method (Hougee, 2013).

Alongside

The alongside method, also referred to as quayside, pier side, or floating method, is a method to dismantle ships that are afloat and moored along wharfs, jetties, or quays and/or moored offshore (Hougee, 2013) (Fig. 8). Cranes and either automated cutting gear, such as mechanical shears or gas cutting torches, are used to reduce the ship in a planned and structured manner. The process is "top-down," i.e., the superstructure and upper pieces are removed first, then the work continues along the ship into the engine room until only the double bottom is left (LR, 2011). This last part of the ship, an empty floating hull called the canoe, is reduced to the extent possible, while afloat and then either taken out as a whole or further cut into pieces in a drydock (Hougee, 2013). This method is mainly practiced in China, the United States, and Belgium.

Fig. 8 (a) A ship docked alongside for recycling (Author's personal visit to a ship recycling yard in China.). (b) Pictorial representation of the alongside method. Courtesy of Lee, M.A., 2012. Korean perspectives on ship recycling. MSc Thesis, IIIIEE, Lund University.

During alongside recycling, the local impact of any pollution is likely to be increased since there is no tidal dispersal effect. However, this means that concentrations can be properly monitored, contained, and cleaned if necessary (LR, 2011).

Drydock

In this method ships are dismantled at a drydock, floating dock, or a slipway that has a lock gate and an impermeable floor structure (Hougee, 2013). This method is the safest and cleanest way of recycling a ship because chances of polluting surrounding waters by accident are virtually nil as everything is contained within the dock (Lee, 2012). The dock is cleaned before it is flooded for dismantling the next ship in order to avoid accumulations of contaminants (LR, 2011). The only downside of this method is that it is the most costly method of recycling a ship, which makes it the most scarcely used. In 2011, Leavesley International's facility in Liverpool was reportedly the one of the main drydock recycling locations in the United Kingdom (LR, 2011). Currently, Able UK Limited, Harland and Wolff Heavy Industries Limited (Fig. 9) and Swansea Drydock Limited are reportedly using the drydock recycling method in the United Kingdom (EC, 2016).

Classification according to the level of mechanization

The classification of recycling methods as per the level of mechanization can be carried out into the non-mechanized process, the highly mechanized process, and the intermediate process (Dev, 2010).

The non-mechanized process

This type of process is generally used in the Indian subcontinent yards. It uses a large amount of workforce and a bare minimum of mechanical equipment to carry out the recycling process. It thrives in places where abundant cheap labor is available and low level

of economic development hinders the use of capital intensive mechanical equipment and infrastructure, such as slipways, jetties, waste collection, and treatment technologies, etc. (Dev, 2010). The lack of health, safety, and environmental regulations also encourages this type of process.

The recycling process begins with the beaching of the ship and pulling it on the “plot” using winches. The ship is then taken over by a team of laborers who carry out the cutting operation using the oxy-acetylene blowtorches. Before starting the cutting process, they also carry out the cleaning of the ship’s tanks containing fuel oil, diesel oil, sludge, etc. and ship’s hull by removing insulation, machinery, loose items, such as furniture, etc. without much use of mechanical means. The cleaning of ship tanks and hull sometimes takes place without even using the protective gears, such as helmets, gloves, safety shoes, overalls, etc., while the lifting operations are carried out by bare-handed laborers (Dev, 2010).

The highly mechanized process

This type of process is generally found implemented in European ship recycling yards. It uses very little labor force. It thrives in places where labor is expensive and health, safety, and environmental regulations are in place. The dismantling process takes place either alongside or in a drydock for a greater control of the entire operation. The cutting operation is carried out using mechanical shears. The use of blowtorches is restricted to cutting jobs that are not possible to carry out using mechanical means. The lifting and transferring of large blocks, machinery, and other loose items to the secondary cutting area on the pier is carried out using the quayside gantry cranes. The ship’s hull and tanks are cleaned by using proper equipment and taking required safety precautions. The dismantling process is interrupted whenever required to achieve safe and environmentally sound operation. The process is environmentally and socially reliable because it uses standardized work practices and equipment that are able to control human and environmental risks (Dev, 2010).

The intermediate process

This type of process is generally used in the ship recycling yards located in China, Turkey, and even at some facilities in the United States (Dev, 2010). It uses both labor and mechanical equipment for the dismantling process. Although the cutting operation is generally carried out using gas torches, the lifting operations are carried out using cranes. This prevents harsh working conditions for the workers. The use of infrastructure, such as slipways, floating docks, quays, etc., provides a reasonable control over the recycling process, which ensures better safety of the workers and the environment.

Business Details

Ship owner’s perspective

Once a ship owner decides to recycle a ship, the standard procedure is to choose one of two strategies: either sell the ship directly to a ship recycling yard or sell it through a cash buyer. Most ship owners prefer to choose the latter strategy because cash buyers pay a lump sum to the ship owners in cash in advance, and charge about 3% commission to close the deal (Engels, 2013). The cash buyers are important intermediaries forming a link between the ship owners and the ship recyclers. As they negotiate the price with the owner, they generally negotiate with several recycling yards at the same time. In some cases, they buy a ship without negotiating a firm deal with a yard. In any case, they bear all the financial risk since they sign a contract and pay the owner till they get paid for delivering a ship to a recycling yard (Krishnaraj, 2015; LR, 2011). Therefore, about 80% of the transactions follow the cash buyer route (Alcaide et al., 2016) as it provides ship owners a sense of financial security, contrary to the distress of settling a deal with a letter of credit, while selling a ship directly to a ship recycling yard (Engels, 2013). The price offered to a ship owner is always in terms of USD per light displacement tonnes (LDT).

The cash buyers purchase obsolete ships from the ship owners on one of the two conditions, either “as-is where-is” or “on delivery” (Jain et al., 2016). With the “as-is where-is” contract, the cash buyer takes over the ownership of the ship from its last port of call till it reaches the ship recycling yard. In this case, the cash buyer usually changes the crew, reflags the ship, and subsequently delivers the ship at his risk to the recycling yard (Engels, 2013). In the case of “on delivery” contract, the ship owner is responsible for the delivery of the ship to the recycling yard in lieu of the guidance from the cash buyer on the best available market rate for the given specifications of the ship (Engels, 2013).

The approach of selling an EOL ship directly to a recycling yard may not always deliver the best results for a ship owner. This is firstly because ship owners lack the specific knowledge of the ship recycling market as they do not sell obsolete ships quite often and secondly because not many recycling yards buy ships directly from the ship owners (Ahuja, 2012; Engels, 2013). More importantly, most deals with a ship recycling yard involve a letter of credit as a payment instrument, which is not preferred by ship owners as they seek quick cash for disposing of the EOL ships.

In either case, whether a ship is sold directly to a recycling yard or through a cash buyer, more often than not a ship broker acts on behalf of the ship owner to negotiate the deal and to manage the business transaction. Shipbrokers are different from cash buyers in their mode of operations as they work directly on behalf of the ship owner and negotiate with cash buyers or ship recycling yards to find the best price for the owner (Krishnaraj, 2015). It is customary for shipbrokers and cash buyers to use their own contracts when dealing with ship owners selling vessels for demolition. However, BIMCO, the largest international association of ship owners provides a standard contract for sale and purchase of ships for demolition. It is called DEMOLISHCON (BIMCO, 2016).

In recent years, there is a growing trend among ship owners to use the services of so-called ship recycling consultants, which are companies specializing in monitoring the entire process of ship recycling from the time ship reaches the recycling yard till it is completely dismantled. They act on behalf of ship owners to ensure that a ship recycling yard follows procedures accepted by international regulations governing the ship recycling industry and relevant health, safety, and environmental standards. The use of ship recycling consultants allows ship owning companies to ensure that their corporate social responsibility (CSR) policy is well implemented.

Ship recycler's perspective

As far as business details of a ship recycling yard are concerned, it is important to understand the cost and revenue generating factors of recycling a ship. Beside fixed capital costs and cost of purchasing a ship, a ship recycling yard must pay variable costs like taxes, government duties, premises rent, labor costs, cost of consumables including electricity, waste disposal costs for both hazardous and nonhazardous waste generated in the dismantling process, and so forth (Sarraf, 2010).

The revenue generated by a ship recycling yard depends on what types of materials can be extracted from a ship and out of those extracted, what and how much can be classified and sold as recyclable material and reusable material. Such classification mainly depends on applicable local and international regulations and local market for reusable goods and scrap metals, such as steel, nonferrous metals, etc.

The markets for reusable goods and scrap products differ from one country to another. In the advanced European countries, steel scrap is generally completely melted down to make new steel products whereas in the Far East and Indian subcontinent, steel scrap is sometimes simply heated and rerolled in reinforcing rods for use in the construction industry including sewage projects, metal roads, and agriculture projects (Stopford, 2009; Sujaudhin *et al.*, 2016). In such countries, there is also a very strong demand for equipment and items reclaimed from ships. This includes diesel engines, generators, air compressors, deck cranes, compasses, clocks, and even furniture. They are generally refurbished by specialized firms and sold to other shore-based industries and interested buyers (Rahman and Mayer, 2015).

Material Composition of EOL Ships

An EOL ship is a complex structure comprising of various systems and structures containing numerous materials including ferrous, nonferrous, plastics, wood, oil, gas, chemicals, hydraulics, and hazardous materials. The material streams originating from dismantling an EOL ship can be grouped into three main disposal categories, i.e., materials or products for resale or reuse, materials or products to recycle, and waste (hazardous/nonhazardous).

The assessment of waste streams and their quantity as a result of dismantling a ship can be done by classifying a ship into the following three segments (Andersen *et al.*, 2001):

1. cargo spaces,
2. machinery spaces, and
3. accommodation spaces.

The cargo space is a large low density area of a ship. It is bounded by ships structure containing mostly only pipework and outfit items, such as ladders and hatch covers. Also, a limited amount of cabling, instrumentation, and selected machinery items may be found (Andersen *et al.*, 2001).

The machinery space is represented by steel structure comprising high-density areas containing mainly pipework and heavy machinery, such as main engine, generators, and auxiliary machinery. These areas also contain significant electrical cabling, electronic equipment, instrumentation, insulation, and outfit steel (Andersen *et al.*, 2001).

The accommodation space is also a high-density area. It is surrounded by steel structure comprising outfitting items related to furniture, furnishings, and sanitation within joinery subdivided areas. Electrical and electronic equipment and controls are found in the navigation and domestic areas of the accommodation space. These areas contain complex utility provision involving pipework, electrical cabling, ventilation trunking, and comfort insulation (Andersen *et al.*, 2001).

These areas of the ship, when dismantled for recycling, generate a material stream containing a mixture of materials including the following (UNEP, 2003):

1. ferrous and nonferrous scrap including coatings;
2. components: machinery, electrical/electronic equipment, joinery, minerals, plastics;
3. consumables: oils, chemicals, gases; and
4. hazardous wastes: asbestos, coatings, polychlorinated biphenyls (PCBs), materials, such as electronic waste, which may be hazardous depending on its components.

Every material stream is composed of different products and components that can either be sold for reuse or can be recycled. The products that do not fit in any of this category are usually disposed of either by landfill or incineration. The following is a comprehensive list of item-groups typically sold in the second-hand market for reuse (Andersen *et al.*, 2001; UNEP, 2003; Hjelmeland, 2009):

Table 1 Downstream disposal options of various waste types

<i>Waste types</i>	<i>Treatment/disposal route</i>
Asbestos	Landfill, solidification, vitrification
Polychlorinated biphenyls (PCBs)	High-temperature incineration, chemical, dechlorination
Ozone depleting substances	High-temperature incineration
Antifouling materials	Solidification, landfill
Cadmium	Physiochemical treatment, landfill
Chromium	Physiochemical treatment, landfill
Lead	Chemical treatment, landfill
Mercury	Chemical treatment, landfill
Radioactive substances	Recovery, secure landfill
Paraffin	Incineration
Bilge water	Physiochemical treatment, landfill
Electrical equipment	Recycling, residues to landfill
Fiberglass	Landfill
Fluorescent tubes	Mercury, glass recovery
Lead acid batteries	Recycling and physiochemical treatment, residues to landfill
Waste oil	Incineration
Oily water	Physiochemical treatment
Pyrotechnics	High-temperature incineration
Sludge	Incineration

Source: Watkinson, R., 2012. Waste management in ship recycling yards. In: Seminar on Ship Breaking and Ship Recycling in Bangladesh and Compliance With International Regulations. Dhaka: Department of Naval Architecture & Marine Engineering, Bangladesh University of Engineering & Technology.

1. steel components (anchors, chains, ventilation components, pipework, etc.),
2. pumps, valves, electric motors, machines (compressors, generators, engines, cranes, etc.),
3. navigational equipment,
4. life-saving equipment (rafts, lifebuoys, life-vests, survival suits, etc.),
5. personal protective equipment (helmets, work boots, gloves, goggles, overalls, etc.),
6. sanitary equipment (toilets, sinks, bath tubs, etc.),
7. household appliances (TVs, DVD players, refrigerators, etc.),
8. chemicals and paints,
9. furniture (beds, chairs, tables, etc.),
10. electrical cabling (intact),
11. batteries,
12. insulation material, and
13. lubricants (on drum), oil products (to manufacturing industries).

A major challenge in the ship recycling industry lies in the disposal of hazardous waste, such as asbestos, PCB, heavy metals, etc. Every country has its own national regulations governing hazardous waste disposal. In some countries asbestos, despite being hazardous, is reprocessed by manual crushing and sold to manufacturing industries (UNEP, 2003). The hazardous materials originating from EOL ships are sent to downstream waste disposal facilities, which may or may not be a part of the ship recycling yards. According to Watkinson (2012), likely downstream disposal options of various waste types are summarized in Table 1.

In general, the material composition of an EOL ship can be classified into the following main elements described in the subsequent sections of the article.

Ferrous Scrap Metal

"Ferrous scrap from ships comes from forgings and castings, shell plating, framing, deck plating and beams, bulkheads, pillars and girders, miscellaneous hull steel, foundations, and steel superstructures. In addition, some structural steel outfit, hull attachments, doors and hatches, deck outfit, steward's outfit, hull engineering items, piping, and miscellaneous machinery are ferrous scrap" (USEPA, 2000) (Fig. 10).

Steel scrap represents the largest recyclable fraction from the merchant ships and is commonly classified as ferrous scrap, of which the largest proportion is carbon steel (Andersen *et al.*, 2001), described as the number 1 melting scrap in the scrap trade (USEPA, 2000). The scrapping facility may recycle scrap metal by selling it to a RESM-Selting/erolling company or to a scrap metal broker for remelting.

When dismantling a ship it is possible to separate flat plates, and girders, beams, and angle bars, from smaller and irregular pieces of metal. At present, there is an international standard maximum size for steel scrap of approximately 1.5 m × 0.5 m × 0.5 m (Andersen *et al.*, 2001). The irregular pieces are fed to the electric arc furnace plants for remelting, while flat plates, girders, beams, and

Fig. 10 Pile of steel scrap as a result of ship recycling operation at a ship recycling yard (Author's personal visit to a ship recycling yard in China.).

angle bars can either be used directly in construction or road building, or can be heated and rerolled into bars and rods in rerolling mills (Mikelis, 2013b). Rerolling plates must be cut from between the ribs of the ship, while beams and other rolled sections are also torched. For example, an H-beam can be cut into three long strips, subsequently to be rerolled into reinforcing bars or fencing (Nijkerk and Dalmijn, 2001). About 60–70% of the steel of a tanker and 50–65% of a bulk carrier is rerolling plate (Mikelis, 2012). Rerolled steel is ideal for sewage projects, metal roads, and agricultural needs (Mishra and Mukherjee, 2009).

Machinery from recycled ships, when it is beyond repair and is of no further use, is also cut and sold as steel scrap. Because the chemical composition of the steel used in shipbuilding is controlled by classification society rules and surveys, ship steel has good yield strength, ductility, and impact strength. Ship steel scrap is therefore attractive for steel making (Mikelis, 2013b).

Steel scrap is usually derived from the ship by using oxy-acetylene gas torches to cut ship's structure in top-down sequence. During ship scrapping, the upper decks including superstructure of the ship are cut first, followed by the lower decks and structures. As large parts of the ship are cut away, they are lifted by crane to the ground where they are further cut into the shapes and sizes required by smelter or scrap metal broker.

Nonferrous Scrap Metal

Nonferrous metals are particularly valuable as they can recover a substantial amount of the price paid by the recycler for the ship. While there are many kinds of nonferrous scrap, one of particular interest is copper-yielding scrap, i.e., cuprous scrap. Cuprous scrap can be classified into bronze, brass, and various other copper alloys. Copper is a high value commodity for which recycling markets exist for reclaiming scrap copper.

One of the major sources of copper in a ship is electrical cabling (Fig. 11). According to certain estimates (Mishra and Mukherjee, 2009), on an average sized ship there are about 50,000 m of cables containing about 40,000 kg of copper. Such cable is recycled by stripping off the insulated covering and other layers to recover the copper. The resulting copper can be sold as scrap and the insulation material would add to the relevant waste stream. Alternatively the cable can be sold to an intermediary for such separation.

Another main source of copper is transformers and electric motor windings. Copper may also arrive from the waste stream of electrical and electronic equipment. Copper pipework can be sold directly unless highly contaminated. Special bronze alloys used in the manufacturing of propellers are equally valuable and are sought after in the recycling market.

Other nonferrous metals recovered from scrapping a ship include aluminum and zinc. Anodes, mainly of aluminum and zinc, are fitted to both the vessel's hull and inside tanks in order to protect against corrosion and fouling. Anodes are sacrificed over the lifetime of the ship and the amount of metals left when the ship arrives for scrapping are removed and sorted for reuse/resale (Andersen *et al.*, 2001). The quantities remaining are likely to vary between 30 and 70% of the initial weight, depending on the time spent on the high seas (Mishra and Mukherjee, 2009). Heavily corroded anodes are disposed of as waste, if recycling is not a feasible option.

Machinery

There are many machinery items on board a ship, including large items, such as the main engine, auxiliary generators, air compressors, and boilers, and smaller items, such as pumps, separators, centrifuges, and heat exchangers (Fig. 12). These machines have metal bodies and most ship machinery could be categorized as resaleable to earn revenue. Main engines, owing to their large size, are likely to be dismantled into smaller components. Specialist operators exist that take machinery for recycling (Andersen *et al.*, 2001)

Fig. 12 Machinery recovered from ship recycling (Author's personal visit to a ship recycling yard in China.).

but machinery that cannot be sold in the second-hand market either due to its obsolescence or due to its irreparability is considered as ferrous scrap and can be sold to RESM-Selters for melting (USEPA, 2000).

Electrical and Electronic Equipment

There is no existing scrap market for waste electrical and electronic equipment (WEEE) within Europe and its disposal is subjected to EU directive. Equipment that is not built-in, for example, a PC or TV, would be covered and subject to the producer responsibility requirements of the WEEE Directive. However, equipment that is part of another type of equipment not covered by the WEEE Directive (e.g., a ship) is itself not within the scope of the WEEE Directive (DEFRA, 2007). Examples of this are installed lighting or built-in radios/GPS equipment, etc.

On the other hand, light fittings, such as tube lights (more than 500 in number on a ship), heavy electrical equipment, such as generators, transformers, and electrical motors, and light electrical equipment, such as switches, radios, radar, etc. are sold in the second-hand market in subcontinent countries, such as Bangladesh, Pakistan, and India (Mishra and Mukherjee, 2009), where most of the world's ship recycling activity takes place. Resale value of generators derived from ships is about USD 24 per kilovolts (KV) in the second-hand market in India (Mishra and Mukherjee, 2009).

Minerals

A wide range of minerals are found on board including asbestos and mineral wool for insulation, ceramics for domestic sanitary items, concrete, tiles, etc. Certain items, such as intact insulation material, ceramics, crockery, etc., might be sold in the second-hand market as per the demand but most of it is regarded as waste. Specifically there are some mineral wastes, such as asbestos, that are classified as controlled or hazardous wastes for which specialist disposal would be required (Andersen *et al.*, 2001).

Fig. 13 Lifeboats obtained from end-of-life (EOL) ships. Reproduced from Mikelis, N., 2012. The emergence of an international regulatory regime for the ship recycling industry. In: Lloyd's Maritime Academy Sale and Purchase Conference, London, reprinted with the author's permission.

Asbestos, in some facilities, is reprocessed by manual crushing and sold to manufacturing industries (UNEP, 2003). Asbestos-containing material (ACM) may be found in thermal system insulation and on surfacing materials. Some other applications in the form of packing, brake linings, fire blanket, etc. may also be found (USEPA, 2000).

Plastics

Plastic materials used on ships are particularly found in accommodation areas. Plastics used in furniture and fittings are mostly unsuitable for recycling as they are likely to comprise of several polymers or to be contaminated with other materials, such as textiles or metals. Therefore, the majority of the plastic waste streams from vessels generally require disposal. Certain specific items, such as cable coverings, may be suitable for recycling, while lifeboats can be reused thus can be sold as demand exist (Fig. 13).

Liquids, Chemicals, and Gases

As discussed by Andersen *et al.* (2001), "the ship's piping and tank arrangements generally contain some quantities of oil, fuel, sludge and associated residues. Fuel oil may be found in both integrated and free-standing tanks throughout the ship. Lubricating oils may be found in a variety of tanks depending on their individual use. Lubrication oils may also be stored in drums. Tanker ships may arrive at the scrapping facility with a significant quantity of cargo residues. Further, all tanks may contain a certain level of sludge."

Coolants and refrigerants are also found on various systems on board ships (Fig. 14). Chemicals that are generally found on board include glycol, chemicals for injection, AFFF foam, dry powder in fire extinguishers, solvents/thinners, battery electrolyte, evaporator dosing and descaling acids, corrosion inhibitor, fresh paints, oil dispersants, cleaning agents, etc. (Andersen *et al.*, 2001).

Coolants and refrigerants can often be sold for reuse, while oil and oily sludge can be sold to industries where they are required for energy recovery. Chemicals are generally classified as hazardous waste and are disposed as per the local regulations whereas refrigerants are recovered from ship systems by specialized firms. Paints that have second-hand value can be sold to the second-hand market (Fig. 14).

Bilge and ballast water is also part of this material stream coming out of ship dismantling. Bilge water is stagnant mix of fresh water, seawater, and other liquids that are usually drained to the lowest inner part of the ship's hull called bilge (Mishra and Mukherjee, 2009). During ship scrapping, bilge water is created through the accumulation of rain water (because the decks are open) and the collection of water from fire lines that leak, are left open, or are used to wet down compartments (USEPA, 2000). This water often contains oil, grease, and other pollutants, such as inorganic salts, arsenic, copper, chromium, lead, and mercury (Andersen *et al.*, 2001).

Generally, sea/fresh/brackish water is intentionally pumped into a ship's ballast tanks to adjust ship's draft, buoyancy, trim, and list for maintaining the ship's stability. This water is called ballast water. It may contain pollutants, such as metals (e.g., iron, copper, chromium) and chemical constituents, originating from additives (e.g., flocculants that facilitate the separation of suspended silts) or from contact of the water with the piping systems and ballast tank coatings (e.g., epoxy coatings and rust inhibitors containing petroleum distillates) (USEPA, 2000). Sometimes seawater that is pumped into an empty fuel tank to improve a ship's stability is termed "dirty" ballast (USEPA, 2000). Pollutants in dirty ballast may include residual fuel, fuel additives (e.g., biocides), oil, grease, and metals, such as copper, nickel, silver, and zinc (USEPA, 2000).

Fig. 14 (a) Recovery of refrigerants from ship systems (Reproduced from Rozenveld, W., 2010. Safe & sustainable ship recycling. In: Sustainable Shipping Conference 2010: From the Cradle to the Grave, Miami, reprinted with the author's permission.). (b) Paint cans sold in the second-hand market in Bangladesh. Reproduced from Mikelis, N., 2012. Hong Kong Convention: The Origins of a Convention. World Maritime University, Malmo, reprinted with the author's permission.

Bilge and ballast water is often discharged overboard, or transferred to evaporation pits and onshore tanks according to applicable rules on the basis of their pollution concentration (Andersen *et al.*, 2001).

Joinery

Timber, wood, and associated materials derived from an EOL ship can generally be reclaimed and sold to intermediary resellers but in modern ship designs, most of the joinery products are composite in nature and may be contaminated by vinyl, plastics, rubber, etc. rendering them to be disposed of either by landfill or incineration (Andersen *et al.*, 2001). Most of the joinery and related products are found in the accommodation area of the ship.

Hazardous Materials

Hazardous materials can be a part of any of the material streams discussed so far. It depends mainly on the nature of the material derived from an EOL ship. For example, asbestos can be classified as minerals, while ozone depleting substances can be a part of the waste stream liquids, chemicals, and gases.

Components derived from an EOL ship may contain a number of hazardous materials, which poses environmental, health, and safety issues. Such hazardous materials need special attention and techniques to alleviate their harmful effects on environment and workers. Often, their removal is governed by local regulations of the country where ship recycling takes place. International conventions, such as the Basel Convention, are also applicable.

A hazardous material stream as a result of dismantling a ship may contain the following items:

1. asbestos,
2. ozone depleting substances,
3. PCBs,
4. radioactive substances,
5. antifouling compounds, and
6. heavy metals.

Asbestos

Asbestos refers to a group of minerals that occur naturally as masses of long silky fibers (USEPA, 2000). When crushed, asbestos breaks up into fine fibers that are too small to be seen by the human eye, which is a property contrary to most other minerals. These fibers, if inhaled, can easily penetrate body tissues and be deposited and retained in the airways and lung tissue. This may cause diseases, such as asbestosis, lung cancer, or cancers of the esophagus, stomach, colon, and rectum (USEPA, 2000).

"During ship scrapping, the most significant asbestos concerns for workers arise when removing asbestos-bearing thermal insulation; handling of circuit breakers, cable, cable penetrations; and removing floor tiles (from asbestos in the mastic and in the tile). Additional concerns can arise from handling and removing gaskets with piping and electrical systems, as well as molded plastic parts" (USEPA, 2000).

Ozone depleting substances

Ozone depleting substances that may be found on board ships include halons, CFCs, and HCFCs. CFCs are nontoxic, non-flammable, and stable in the troposphere, whereas in the stratosphere, they can be broken down by UV light and deplete the ozone layer (Andersen *et al.*, 2001). CFCs are used as refrigerants, solvents, and foam blowing agents. The use of CFCs, some chlorinated solvents, and halons (chemicals used as fire extinguishing agents) on board ships should become obsolete in the next decade owing to international maritime regulations, such as MARPOL.

PCBs

PCBs belong to a broad family of man-made organic chemicals known as chlorinated hydrocarbons. Due to their physical and chemical properties, such as nonflammability, chemical stability, high boiling point, and electrical insulating properties, PCBs were used in many industrial and commercial applications including electrical, heat transfer, and hydraulic equipment; as plasticizers in paints, plastics, and rubber products; in pigments, dyes, and carbonless copy paper; and many other applications (USEPA, 2000). "PCBs are found in solid (waxy) and liquid (oily) forms in equipment and materials on ships being scrapped. This includes cable insulation, thermal insulation material, transformers, capacitors, oils, paints and coatings, plastics and rubber, etc." (UNEP, 2003).

PCBs are toxic and they remain in the environment persistently. They can cause a number of adverse health effects to workers through skin contact or inhalation. PCBs can spread to the surrounding environment through the ground and/or water if not handled and disposed of properly (UNEP, 2003).

Cable burning for the recovery of copper wire can generate toxic dioxins. PCB concentration in cables taken from vessels during scrapping can be up to 280,000 ppm (28%) (Andersen *et al.*, 2001), which is critically high. Improper processing of cables in order to extract copper by burning off the insulation (commonly used in scrap facilities in Indian subcontinent countries) may lead to the release of particularly hazardous components to the environment (Andersen *et al.*, 2001).

Radioactive substances

As explained by Andersen *et al.* (2001), "radioactive material may be present on board a ship in liquid level indicators, smoke detectors and emergency signs. These sources generate low level radioactive waste, but handling and disposal of such waste is usually strictly regulated. Ionizing radiation is hazardous to human health and the environment and can cause severe forms of cancer and/or damage to genetic material endangering future generations."

Antifouling compounds

Antifouling paints are applied to the ship's hull to avoid marine growth during the operation of the ship. Such coatings are also applied to the ship's ballast tanks. These paints and coatings are harmful to human health and environment as they contain organometallic substances, such as tributyl tin (TBT), and heavy metals, such as lead and chromium (UNEP, 2003). TBT can cause an effect even at very low concentrations and is therefore considered to be one of the most toxic compounds in the aquatic environment (Andersen *et al.*, 2001). Exposure to hazardous paint fumes during metal cutting is an occupational health hazard. Moreover, paint fumes are also dispersed through the air and may be deposited far away from their source (UNEP, 2003). If a ship is recycled by beaching method, paint is removed to the marine environment due to contact between the ship's hull and the beach (Mishra and Mukherjee, 2009).

Heavy metals

Heavy metals, such as lead, cadmium, barium, chromium, zinc, mercury, etc., are found on board ships from various sources, such as paints, coatings, bilge, ballast water, thermometers, electrical switches, batteries, etc. These heavy metals, if not handled properly, are hazardous to health, safety, and environment.

An extensive discussion on the same by Andersen *et al.* (2001) states that "mercury is a toxic heavy metal and a persistent, bio-accumulative pollutant that affects the nervous system. Accidental spills of mercury can lead to dangerous mercury exposure. Consumption of contaminated fish is also an important route of mercury exposure."

The discussion further continues: "lead is toxic, and is found in batteries, paints and in components in motors, generators, piping, cables and others. Long term exposure to low levels can cause irreversible learning difficulties, mental retardation and delayed neurological and physical development in children. In adults, exposure to lead affects primarily the peripheral nervous system and can cause impairment of hearing, vision, and muscle coordination. Lead also damages the blood vessels, kidneys, heart and the reproductive system" (Andersen *et al.*, 2001).

The estimation of material composition of two major ship types (tankers and bulk carriers) carried out by Andersen *et al.* (2001) is depicted by Figs. 15 and 16. These estimates are based on the sampling of few ships of each ship type. An extensive discussion on quantifying the material composition of EOL ships was carried out by Jain *et al.* (2016), where authors suggested a methodology applicable to all ship types. The existing literature on this topic is also discussed in detail.

Fig. 16 Fractions of each waste stream in a bulk carrier as percentage of total weight of the ship.

Regulatory Overview

As already mentioned above, ship recycling is considered as one of the most dangerous jobs in the world due to a very high rate of accidents and diseases, compared to other industries (Graham-Rowe, 2004). It also has consistently moved to countries where health and safety regulations are minimal. The governments, nongovernmental organizations, and other international organizations around the world have been putting in their efforts to tackle the social and environmental hazards of the ship recycling industry by means of developing and implementing policies and legal instruments to govern the ship recycling industry on a global level. The relevant international legal regimes governing the global ship recycling industry are discussed below.

Basel Convention

The “Basel Convention on the Transboundary Movements of Hazardous Wastes and their Disposal,” hereinafter called the Basel Convention, was adopted in 1989 and came into force in 1992. It is an international convention that was formed to control the movement of hazardous wastes from the developed countries to the developing countries, so that the illegal dumping of wastes by the operating companies can be prevented (BC, 2011b). A follow-up legislation to this convention is the “Ban Amendment.” It prohibits the transportation of wastes from an Organisation for Economic Co-operation and Development (OECD) country to a non-OECD country (BC, 2011a). Although this amendment has not come into force, several countries including all the EU countries have ratified it (LR, 2011). The legal position of the Basel Convention and the Ban Amendment at the European level is effectively implemented by the European Waste Shipment Regulations (EWSR) (LR, 2011, Mudgal et al., 2010).

The applicability of the Basel Convention to ships sent for recycling rests upon three elements – first, the ships have to be classified as waste; second, they have to be subject to transboundary movement; and third, both the state of export and the state of import have to be parties to the Basel Convention (Engels, 2013). As 179 states including all member states of the EU as well as all the major recycling states are party to the Basel Convention and transboundary movement of a ship is self-evident in its sale and purchase transaction, the only remaining question to answer is whether an EOL qualifies as “waste” or not. Bhattacharjee (2009), Engels (2013), Moen (2008), and several others have extensively discussed the fact that the Basel Convention considers an EOL ship that is meant for export and contains hazardous materials in its structure as “hazardous waste.”

However, due to the global nature of the shipping industry and the practices associated with sending EOL ships for recycling, there has been difficulty in applying the provisions of the Basel Convention to ship recycling and often ship owners are found to circumvent the Convention (BC, 2011b; Bhattacharjee, 2009). Two of the major hurdles to the effective application of the Basel Convention are the challenges in identifying in practice when a ship becomes waste, and identifying which country is to be regarded as the "State of export" under the Basel Convention (Bhattacharjee, 2009). These difficulties in the implementation of the Basel Convention culminated the need for a separate mandatory international regime, specifically designed to meet the unique requirements of the global ship recycling industry, and thus led to the development of the HKC at the IMO.

HKC

The Hong Kong International Convention for the Safe and Environmentally Sound Recycling of Ships, commonly known as the HKC, was adopted at a diplomatic conference held in Hong Kong in May 2009 (IMO, 2009). However, it is not yet in force; to date, only four countries – Belgium, France, Congo, and Norway – have acceded to the Convention. Recently, the Danish, Panamanian, and Turkish governments took necessary legal steps to accede to the Convention (Danish Shipowner's Association, 2016; Green4sea, 2017). The accession by Panama and Turkey would be a big step for the Convention to come into force as per the conditions set out by IMO for its entry into force.

Entry into force criteria

The requirements for its entry into force, as per the Article 17 of the Convention, include the following (IMO, 2009):

"The Convention shall enter into force 24 months after the date on which the following conditions are met:

1. not less than 15 States have either signed it without reservation as to ratification, acceptance or approval, or have deposited the requisite instrument of ratification, acceptance, approval or accession in accordance with Article 16;
2. the combined merchant fleets of the States mentioned in paragraph (1) constitute not less than 40% of the GT of the world's merchant shipping; and
3. the combined maximum annual ship recycling volume of the States mentioned in paragraph (1) during the preceding 10 years constitutes not less than 3% of the GT of the combined merchant shipping of the same States."

These requirements effectively mean that apart from the major shipping states with flags of convenience (Panama, Liberia, Marshall Islands, etc.), ratifications by at least two of the three main recycling countries (India, Bangladesh, China) are required for the Convention to be applicable (Ormond, 2012). The slow progress of the HKC toward attaining its entry into force criteria has created a skepticism amongst the stakeholders about the convention's entry into force in the near future (Cameron-Dow, 2013).

Applicability

The HKC adopts the approach of dual application covering both the ship and the ship recycling facility, which is a comprehensive approach to deal with the problems relating to human health, safety, and environmental protection associated with the process of ship recycling (Jain *et al.*, 2013). The definition of a "ship," as given in the Convention, explicitly includes submersibles, floating crafts, floating platforms, among other offshore and storage vessels including vessels being towed or stripped of equipment. The HKC exempts ships less than 500 GT, ships operating throughout their life only in waters of the state whose flag they are entitled to fly (inland waterway vessels), warships, naval auxiliaries, and other ships not used for commercial purposes from the scope of its application. It defines the ship recycling facility as an area that is a site, yard, or facility used for the recycling of ships.

Key elements and procedures

The aim of the HKC is to ensure that the ships recycled at the end of their operational lives do not pose any unnecessary risk to human health and safety or to the environment. The structure of the Convention is depicted by Fig. 17. It contains 21 articles setting out the general legal provisions and working mechanisms, and an annex containing 25 regulations and 7 appendices, forming the essential requirements and technical details of the Convention (IMO, 2009). The regulations are divided into four chapters, i.e., general provisions (Regulation 1–3), requirements for ships (Regulation 4–14), requirements for ship recycling facilities (Regulation 15–23), and reporting requirements (Regulation 24–25). The appendices contain a list of hazardous materials and a range of forms and checklists, which are supposed to facilitate compliance with the provisions of the Convention (Jain *et al.*, 2013; Ormond, 2012).

It is supplemented by a set of following six guidelines:

1. guidelines for the Development of the Ship Recycling Plan (SRP) (Annex 2) (IMO, 2011b);
2. guidelines for the Development of the Inventory of Hazardous Materials (IHM) (Annex 3) (IMO, 2011a);
3. guidelines for the Safe and Environmentally Sound Ship Recycling (Annex 4) (IMO, 2012a);
4. guidelines for the Authorization of Ship Recycling Facilities (Annex 5) (IMO, 2012b);
5. guidelines for the Survey and Certification of Ships under the HKC (IMO, 2012d); and
6. guidelines for the Inspection of Ships under the HKC (IMO, 2012c).

Fig. 17 Structure of the Hong Kong Convention (HKC).

Table 2 Impact of International Maritime Organization's Hong Kong Convention (HKC) on various stakeholders

<i>Recycling state</i>	<i>Ship recycling facility</i>	<i>Ship owner</i>	<i>Flag state</i>
• Authorize the ship recycling facility by issuing Document of Authorization to Conduct Ship Recycling (DASR) • Approve the Ship Recycling Plan • Send a copy of the Statement of Completion to the Flag State	• Prepare a Ship Recycling Facility Plan • Develop a ship-specific Ship Recycling Plan • Notify the Competent Authority (CA) of the planned start of recycling a ship • Notify the CA the completion of the ship recycling by issuing the Statement of Completion	• Always keep an Inventory of Hazardous Materials (IHM) on board the ship • Finalize the ship's IHM before sending it for recycling • Provide ship related information to the ship recycling facility	• Verify IHM, Ship Recycling Plan (SRP), and DASR

These guidelines are designed for proper implementation of the requirements of the HKC unlike other existing non-mandatory guidelines related to ship recycling developed by ILO, IMO, and the Basel Convention.

The HKC, whenever enforced, will create certain obligations for various stakeholders including ship owners, ship recycling yards, flag states, recycling states, port states, etc. as shown in [Table 2](#). It makes mandatory for concerned ships to carry an IHM in accordance with its requirements. It also imposes restrictions on the installation or use of certain hazardous materials (listed in an appendix) in shipyards, ship repair yards, and ships of parties to the Convention. The IHM shall be regularly updated and certified by the Flag State using the International Certificate on Inventory of Hazardous Materials (ICIMH).

The concerned ships are required to be sent for recycling only to the authorized ship recycling facilities. The authorization of the ship recycling facilities is subject to the inspection by the authorities of Recycling State and issuance of a Document of Authorization to Conduct Ship Recycling (DASR). The authorized recycling yards are obliged to develop a Ship Recycling Facility Plan (SRFP) in accordance with the requirements of the Convention. They are also required to develop a ship-specific SRP, specifying the manner in which each ship will be recycled. The SRP shall be developed on the basis of the ship's IHM and other ship related relevant information provided by the ship owner. The responsibility to approve a SRP lies with the Competent Authority (CA) appointed by the Recycling State.

The Flag State is required to issue an International Ready of Recycling Certificate (IRRC) after verifying the ship's IHM, DASR of the recycling facility, and the approved SRP. After the completion of recycling, the Recycling State shall issue a Statement of Completion of Ship Recycling, marking the end of the recycling process in accordance with the HKC. Subsequently, the Recycling State is required to send a copy of the statement to the Administration that issued the IRRC for the ship. The HKC empowers the Port State inspectors to undertake investigations of the ships calling their ports to ensure the adherence to the Convention. They can even detain, dismiss, or exclude a ship from their ports as a result of a violation.

EU Ship Recycling Regulation

The EU Regulation No. 1257/2013 on ship recycling, commonly known as EU Ship Recycling Regulation (EUSRR), was formally adopted by the European Parliament and the Council of the EU on November 20, 2013. It entered into force on December 30,

2013, 20 days after it was published in the *Official Journal of the European Union* (EU, 2013). It is similar to the HKC in most aspects and does not contain any contradictory provisions that could impede the prospects of HKC getting entered into force; in fact, it is likely to support an early implementation of the HKC as this regulation is bound to be applicable by December 31, 2018 at the latest (EU, 2013; Mikelis, 2013a). However, few of its requirements will be applicable only by December 31, 2020, at the latest (EU, 2013).

Unlike HKC, EUSRR has distinct dates for its entry into force and its application. The date of application is the date after which the provisions of the EUSRR are legally applicable. The main provisions of the EUSRR are as under:

1. Its application is restricted to the ships flying the flag of a Member State of the EU and to the vessels with non-EU flags that call at an EU port or anchorage. The ships visiting the EU ports are required to keep an IHM, prepared in accordance with its requirements. The exemptions in this regard are similar to the HKC. It also sets out responsibilities for ship owners and for recycling facilities both in the EU and in other countries.
2. The requirements for the IHM are similar to the HKC except for the inclusion of perfluorooctane sulfonic acid (PFOS) and its derivatives in Annex I and brominated flame retardant (HBCDD) in Annex II of the list of the hazardous materials (EU, 2013; Mikelis, 2013a). Annex I lists the prohibited hazardous materials whereas Annex II lists the hazardous materials which must be included in the IHM.
3. Other requirements related to the SRP, the SRFP, certification (IHM certificate and ready-for-recycling certificate), statement of completion, etc. are similar to the HKC, except that the approved recycling facilities (both EU and non-EU) will be included in the "European List" to be published by the European Council in the *Official Journal of the European Union* no later than December 31, 2016. In fact, first list was published on December 19, 2016 (EC, 2016). This list shall be the first point of reference for the ship owners of EU-flagged ships as they are obliged to recycle their ships only in an approved ship recycling yard. The list will be regularly updated to include or remove ship recycling facilities, as appropriate.
4. To get approved, recycling facilities will have to comply with the provisions of the HKC and also with the following three additional requirements (EU, 2013; Mikelis, 2013a):
 - "operate from built structures";
 - demonstrate "the control of any leakage, in particular in intertidal zones";
 - ensure "the handling of hazardous materials and of waste generated during the ship recycling process, only on impermeable floors with effective drainage systems."

Green Ship Recycling

With the development of international ship recycling regulations discussed above, several recycling yards around the world coined the term "green" recycling to make themselves distinct from other yards. In general, there is a common understanding among the industry stakeholders that recycling a ship with procedures to safeguard the environment and workers' health and safety in place can be called green ship recycling, as discussed by the World Bank (Sarraf, 2010) and the EC (2007). However, using a set of criteria, based on the international ship recycling regulations (HKC and EUSRR), to recognize a green ship recycling yard would be a more pragmatic approach. Therefore, the following criteria, based on Chapter 3 – "Requirements for Ship Recycling Facilities" of the HKC and Article 13 – "Requirements necessary for ship recycling facilities to be included in the European List" of the EUSRR (EU, 2013; IMO, 2009) are identified.

For a ship recycling facility to be called "green,"

1. it should be authorized by the Competent Authority (CA) of the Recycling State to conduct the ship recycling operations;
2. it should prepare a ship recycling facility plan as per the requirements of the HKC;
3. it should operate from the built structures, as defined by the technical guidance note of the EUSRR (EU, 2016);
4. it should establish management and monitoring systems, procedures, and techniques to prevent, reduce, minimize, and to the extent practicable, eliminate health risks to the workers concerned and to the population in the vicinity of the ship recycling facility, and adverse effects on the environment caused by ship recycling (EC, 2013; IMO, 2009), which includes:
 - prevention of fires and explosions by ensuring safe-for-hot-work conditions are maintained and monitored throughout ship recycling;
 - prevention of dangerous conditions by ensuring safe-for-entry procedures are in place to maintain and monitor the atmosphere of confined and enclosed spaces on ship throughout the ship recycling;
 - prevention of accidents, occupational diseases, injuries, spills, or emissions and other adverse effects that may harm human health and environment;
5. it should ensure safe and environmentally sound management and storage of hazardous materials and waste in accordance with the requirements of the HKC and EUSRR, i.e.,
 - containment of hazardous materials present on board during the entire process of recycling;
 - handling of waste and hazardous materials on impermeable floors with effective drainage system;
 - record keeping of the quantity of waste generated during ship recycling and its disposal at authorized waste management facilities only;

6. it should establish and maintain an emergency preparedness and response plan, and ensure rapid access of emergency response equipment, such as fire-fighting vehicles, cranes, ambulances, etc., to ship and all areas of ship recycling facility;
7. it should train the workers and provide them with personal protective equipment; and
8. it should record and report (if required) the incidents, accidents, occupational diseases, and chronic effects causing risks (or have the potential to cause risks) to workers' safety, human health, and the environment.

Concluding Remarks

This article described the current state of the global ship recycling industry. It provides answers to the questions such as, when ships are recycled, why ships are recycled, what are the locations at which ships are generally recycled and in what volumes, what methods are used to recycle ships in various countries, what are the business details of the ship recycling transactions, and which international regulations govern the ship recycling industry. It also described the impact of upcoming international regulations on various stakeholders. The criteria that can be used to identify a green ship recycling yard are also defined in this article.

Acknowledgment and Disclosure

This article is based on Chapter 2 of the first author's PhD dissertation entitled "*Improving the Competitiveness of the Green Ship Recycling*" (<http://doi.org/10.4233/uuid:3e74dea2-c01b-4b23-8194-2faec501a3c7>). The research for the same was carried out at Delft University of Technology, The Netherlands for a project collaboration with Tianjin University, China and International Ship Recycling Association, The Netherlands. The project was funded by Gieskes Strijbis Fonds and Lloyd's Register.

Plastic Products in Hospitals and Healthcare Systems

Osama M Basmage and Mohamad SJ Hashmi, Dublin City University, Dublin, Ireland

© 2020 Elsevier Inc. All rights reserved.

Introduction

Plastic products have significantly impacted applications in hospital and healthcare systems and have made substantial improvements. Plastic is any material that is part of a wide range of semisynthetic or synthetic solids that are used in the manufacture of different products ([Plastic use in Medicine, 2013](#)). The word *plastic* is derived from the Greek *πλαστικός* (*plastikos*) meaning “capable of being shaped or molded” and, in turn, from *πλαστός* (*plastos*) meaning “molded.” ([Lidell and Scott, 2011](#); [Online Etymology Dictionary, 2019](#)).

Plastic has different definitions; one of them is a type of synthetic or manmade polymer, similar in many ways to natural fibers found in trees and other plants. Webster’s Dictionary defines polymer as one of many various organic compounds produced by polymerization, capable of being molded, extruded, cast into shapes and films, or drawn into filaments and then used as textile fibers. ([Life Cycle of a Plastic Product, 2010](#)). While the International Union of Pure and Applied Chemistry (IUPAC) definition of plastic is a generic term used in the case of polymeric material that may contain other substances to improve performance or reduce costs ([Vert et al., 2012](#)).

In many hospitals and medical device applications, materials like metal, wood, glass, and plastics are being used. The 19th and 20th centuries saw an explosion of medical devices, and materials such as stainless steel, titanium, vanadium, ceramic and plastics being used in their manufacturing. The demand for precision instruments for microsurgery in neurosurgery, ophthalmology, and otology was possible, and in the second half of the 20th century, energy-based instruments like electrocauteries, ultrasound, electric scalpels, surgical tools, and surgical robots ([Sastri, 2013](#)).

In general, there are two main types of plastics. The first one is known as natural plastic such as natural rubber, nitrocellulose, collagen, etc. Whereas the second one is the synthetic form such as epoxy, polyvinyl chloride (PVC), Bakelite. Parkesine, the first member of the celluloid class of compound and considered the first manmade plastic, was patented by Alexander Parkes ([UK Patent Office, 2018](#)).

Improvement in chemical technology after World War II led to an explosion in new forms of plastic, with mass production beginning in the 1940s and 1950s ([Richard et al., 2009](#)), and the top 50 plastic companies were in three countries: Germany, Japan, and the United States ([Alexander, 2015](#)). The decades since the 1970s have witnessed the advent of “high-tech” plastic used in demanding fields such as health and technology. New types and forms of plastics with new or improved properties have been created ([American Chemistry Council, 2010](#)). A third of plastic products are used in packaging ([Andrady and Neal, 2009a,b](#)).

The most important advantages of plastic are medical uses and applications for hospitals and public healthcare. Hospitals and healthcare systems see a rich intersection of rigid and flexible plastics and plastic-based medical devices ([Plastic Today, 2017](#)). Plastic are cost-effective, require little energy to produce, and are lightweight and biocompatible ([Proshad et al., 2016](#)). Plastic is soft, transparent, flexible, biodegradable, and many different types of plastics function as innovative materials for use in engineered tissues, absorbed suture, prosthetics, and other medical applications ([Andrady and Neal, 2009a,b](#)).

There are about 20 types of prime plastic in use worldwide ([AMPE, 2006](#)). Plastics play an important role in a more recent, innovative wound care technology: Liquid bandages. These bandages are made from various plastics and a solvent such as water or alcohol.

As the wound heals, the plastic of the liquid bandage sloughs off with the old skin cells. Liquid bandages often are used to replace traditional sutures and staples in surgery – they cause less trauma and do not need to be removed ([American Chemistry Council, 2018a,b](#)). Commodity plastics like PVC, polyethylene (PE), polypropylene (PP), and polystyrene (PS) make up over 70% of the share of plastic used in medical devices ([Sastri, 2010d,e,f,g](#)). Recent advances could lead to even more innovations in healthcare – and help people all around the world. Of these innovation for example the plastic heart (Total Artificial Heart). It is powered by a pneumatic pump that you carry around in a rucksack ([Fong, 2011](#)). A novel use of foam polyurethane plastic may help stabilize trauma patients with serious internal injuries. Painless plastic injections, bacteria-resistant plastics, and plastics could be used to make catheters or medical equipment to help ward off preventable disease. And plastics will continue to help drive innovations in medical care that we only dream about today ([American Chemistry Council, 2017](#)).

General Classification of Plastics

The plastics family is composed of a great variety of materials designed to meet the very different needs of thousands of end products ([Plastic Europe, 2018](#)). So even though the number of plastics is unclear, plastics makers tend to group plastics into two general classes: Thermoplastics and thermosets, as illustrated in [Table 1](#).

Table 1 The two Plastics' family: Thermoplastics and thermosets

<i>Categories of plastics</i>		
<i>Thermoplastics</i>		<i>Thermosets</i>
It is a family of plastics that can be melted when heated and hardened when cooled, and can be reheated, reshaped, and frozen repeatedly.		It is a family of plastics that undergo chemical change when heated, creating a three-dimensional network, and it cannot be remelted and reformed.
Polyethylene	Polycarbonate	Polyurethane
Polypropylene	Poly methyl methacrylate	Unsaturated polyester
Polyvinyl-chloride	Thermoplastic elastomers	Epoxy resins
Fluoropolymers	Polyarylsulfone	Melamine resin
Expanded polystyrene	PEEK	Silicone
ABS	POM	Phenol-formaldehyde
SAN	PBT	Urea-formaldehyde
Polyamides	etc.	Phenolic resins
		Acrylic resins
		etc.

Abbreviations: ABS, Acrylonitrile butadiene styrene; PBT, Polybutylene terephthalate; PEEK, Polyetheretherketones; POM, Polyoxymethylene, or acetal; SAN, Styrene acrylonitrile resin.

Thermoplastics

This family can be remelted and essentially returned to their original sets, sort of like the way an ice cube can be melted and then cooled again. Usually they are produced first in a separate process to create small pellets; these pellets then are heated and formed to make all sorts of consumer and industrial products.

Thermoplastics include PE, PP, PVC, PS, nylon, PC, and others (American Chemistry Council, 2018a,b).

Engineering thermoplastics can be amorphous such as ++ acrylics, PC, and polyurethanes or crystalline such as polyacetals, polyesters, and polyamides (Sastri, 2010a,b,c).

Polyethylene

Polyethylene or polythene (PE), IUPAC name polyethene or poly(methylene), is the most common plastic. As of 2017, over 100 million tons of PE resins are produced annually, accounting for 34% of the total plastics market (Geyer *et al.*, 2017). Many kinds of PE are known, with most having the chemical formula $(C_2H_4)_n$. PE is usually a mixture of similar polymers of ethylene with various values of n .

PE is a thermoplastic; however, it can become a thermoset plastic when modified (such as cross-linked PE) (Plastics Europe, 2017). PE is classified by its density and branching. Its mechanical properties depend significantly on variables such as the extent and type of branching, the crystal structure, and the molecular weight.

There are several types of PE: Ultra high molecular weight polyethylene, Ultra low molecular weight polyethylene, High molecular weight polyethylene, High density polyethylene (HDPE), High density cross-linked polyethylene, Cross-linked polyethylene, Medium-density polyethylene, Linear low density polyethylene (LLDPE), Low density polyethylene (LDPE), Very low density polyethylene, Chlorinated polyethylene. As for sold volumes, the most important PE grades are HDPE, LLDPE, and LDPE. The degree of branching of the different types of PE can be schematically represented as in Fig. 1 (Kaiser, 2011; Panayotov *et al.*, 2016).

Polypropylene

PP is a thermoplastic polymer used in a wide variety of applications. It belongs the group of polyolefins and it has similar properties to PE, but it is slightly harder and more heat resistant. It is white (Whiteley *et al.*, 2005). The global market for PP is about 55 million tonnes (Ceresana, 2019).

There are two main types of PP available: Homopolymers and copolymers. The copolymers family is further divided into block copolymers and random copolymers (McKeen, 2014). Each category fits certain applications better than the others.

They are usually incorporated with anywhere between 1% and 7% ethylene and are selected for applications where a more malleable plastic is needed (Polypropylene PP, 2016). Some of the most common applications are buckets, bowls, crates, toys, medical components, washing machine drums, battery cases, bottle caps, fibers for carpets, and sports clothing (British Plastics Federation, 2019).

Polyvinyl chloride

Polyvinyl chloride or vinyl (PVC) is a polymer in which more than half of the content by weight consists of chlorine (Vesterberg *et al.*, 2005). PVC is produced by polymerization of the vinyl chloride monomer. PVC comes in two basic forms: Rigid (sometimes abbreviated as RPVC) and flexible.

Fig. 1 The figure shows polyethylene backbones, short-chain branches, and side chain branches. The polymer chains are represented linearly. Reproduced from Kaiser, W., 2011. *Kunststoffchemie für Ingenieure von der Synthese bis zur Anwendung*, third ed. München: Hanser.

It is the world's third-most widely produced synthetic plastic polymer, after PE and PP. About 40 million tons are produced per year. Pure PVC is a white, brittle solid (although different PVC variants are designed to be very flexible) and strong (Creative Mechanisms, 2016).

Polystyrene

PS is the simplest plastic based on styrene. PS can be transparent or can be made in various colors. Three general PS types are general purpose or crystal polystyrene, high impact polystyrene, and siderostatic polystyrene.

Nylon

Nylon is a generic designation for a family of synthetic polymers, based on aliphatic or semiaromatic polyamides. Nylon is a thermoplastic silky material that can be melt-processed into fibers, films, or shapes (Kohan, 1995). Nylon polymers can be mixed with a wide variety of additives to achieve many different property variations. Nylon has several types, such as Nylon 66, Nylon 6, and Nylon 510, which have significant commercial applications.

Polycarbonate

PC is a type of polyester but is discussed separately. PC performance properties include very impact resistant, clear as glass, high heat resistance, dimensional stability, resistant to UV light, allows exterior use, and flame-retardant.

Polyacrylate

(Acrylic, Poly methyl methacrylate (PMMA)) While many acrylic polymers are manufactured, PMMA is by far the most common. PMMA has two very distinct properties that set the products apart from others. First, it is optically clear and colorless. They are also highly weather resistant.

Hydrogel (Acrylate)

The acrylic is made from monomers that have hydroxyl (a OH) groups on them that "like" water. One such hydrophilic polymer is poly (hydroxyl ethyl acrylate) or poly (hydroxyl ethyl methacrylate) (PHEMA). Blends of a hydrophobic silicone with a hydrophilic PHEMA produce a lens.

Polysulfone

Polysulfone is a rigid, strong, tough, high temperature amorphous thermoplastic. Its properties are high thermal stability, high toughness and strength, good environmental stress crack resistance, inherent fire resistance, and transparency.

Polyetheretherketone

Polyetheretherketones (PEEK) are also referred to as polyarylktones. It is a thermoplastic with extraordinary mechanical properties. The Young's modulus of elasticity is 3.6 tensile strength is 170 MPa. PEEK is partially crystalline, and melts at around 350°C.

Thermoplastic Elastomers (e.g., Thermoplastic Polyurethane)

An elastomer is a polymer with the property of "elasticity," generally having notably low Young's modulus and high yield strain compared with other materials. The term is often used interchangeably with the term rubber (McKeen, 2014).

Table 2 An example of disposables plastic products in the hospital

Construction products	Doors and windows	Pipes: Water and vent	Roofing membranes
Patient products	Patient ID cards and bracelets	Foot orthoses	Inflatable splints and injury support packs
Furniture products and furnishings	Bed caster, rails, and wheel	Floor covering	Shower curtains
Packaging, medical products	Medical devices	Film wrap	Thermoformed trays for admission and diagnostic kits
Kidney (Renal Disease) therapy products	Hemodialysis: Blood line (tubing) and catheters	Peritoneal dialysis: Dialysate containers (bag) and fill	Peritoneal dialysis Drain lines (tubing)
Entera feeding products	Enteral feeding sets (bags and tubing)	Nasogastric tubes	Tubing for breast pumps
Blood products and transfusion	Apheresis circuits	Blood bags and tubing	Extracorporeal membrane oxygenation circuits
Respiratory therapy products	Aerosol and oxygen masks, tents, and tubing	Endotracheal and tracheostomy tubes	Nasal cannulas and catheters
Office suppliers	Notebook binders	Gloves, examination	Plastic divides in patient charts

Abbreviation: PVC, Polyvinyl chloride.

Thermoset Elastomers

One of the most important thermoset elastomers is silicone, also known as siloxane, polyorganosiloxane, or polysiloxane.

Silicone rubber is a semiorganic synthetic. Its polymer backbone structure consists of a chain of silicon and oxygen atoms rather than carbon and hydrogen atoms, as in the case with other types of rubber.

Poly-*p*-xylylene (Parylene)

Parylene is the generic name for members of a series of polymers. The basic member of the series, called Parylene N, is poly-*para*-xylylene, a completely linear, highly crystalline material. Parylene polymers are not manufactured and sold directly. They are deposited from the vapor phase by a process that in some respects resembles vacuum metalizing.

Fluoropolymers (e.g., PTFE)

Polymer is an example of a linear fluoropolymer. Formed by the polymerization of tetrafluoroethylene (TFE), the (aCF₂aCF₂a) groups repeat many thousands of times. The fundamental properties of fluoropolymers evolve from the atomic structure of fluorine and carbon-carbon bonds and the pendant groups are carbon fluorine bonds. Both are extremely strong bonds (McKeen, 2014).

General Characteristics of Plastics

Each plastic has very distinct characteristics, but most plastics have the following general attributes.

- (1) Plastics can be very resistant to chemicals.
- (2) Plastics can be both thermal and electrical insulators.
- (3) Generally, plastics are very light in weight with varying degrees of strength.
- (4) Plastics can be processed in various ways to produce thin fibers or very intricate parts.
- (5) Polymers are materials with a seemingly limitless range of characteristics and colors.
- (6) Polymers are usually made of petroleum, but not always.

Categories of Plastic Products in Hospitals and Healthcare

Plastic products in hospitals and healthcare can be classified into two major categories. The first category is disposable plastic products such as gloves, blood bags, colostomy bags, bandages, catheters, IV kits, tubing and syringes. The second one is nondisposable plastic products such as devices include machines and instrument, surgical and dental instruments, diagnostic equipment, prostheses, and implants. Table 2 illustrates an example of disposals plastic products in hospitals (PVC products).

Properties of Plastic Products in Hospital and Healthcare Systems

Materials used in nondisposable applications must typically meet long-term durability and stringent physical and mechanical properties. Materials used in machines and diagnostic equipment do not necessarily need to be sterilized or meet specific chemical

Fig. 2 MRI machines. Reproduced from Piedmont Plastics, 2018a. Medical equipment. [Online] (accessed April 2019). Piedmont Plastics, 2018b. What is the best type of plastic for medical equipment? [Online] Available at: <https://www.piedmontplastics.com/blog/82/best-plastics-for-medical-equipment> (accessed April 2019).

resistance or biocompatibility requirements. Examples of diagnostic and surgical equipment are MRI machines (**Fig. 2**), electrocautery devices, and electrocardiogram monitors. Implants on the other hand must meet strict biocompatibility, biodurability, and sterilization requirements to be safe and effective in the body. It is important to know the dimensions, size, and weight requirements for the part or product. Consideration must also be given to the loads, stresses, and impact that the product might see during its use (*Sastri, 2010a,b,c*). Medical devices are getting smaller with more functionality and electronics.

Minimally invasive surgeries, disposables, implants, remote diagnostics, and home healthcare are driving some of these needs. Many additives like fillers, toughness, lubricants, and stabilizers can be used to improve the physical and mechanical properties. Other additives are more specific to medical applications. Radiopaque additives can render plastics visible to X-rays allowing surgeons to view, guide, and place devices in the body. Nanoadditives can be used in small amounts to produce miniature parts and devices that are strong and that incorporate functional characteristics like electrical conductivity, thermal conductivity, barrier properties, and radiopacity and antimicrobial properties. Stabilizers can be used to improve the thermal and radiation stability of plastics. This wide array of additives that can be used in formulating plastics extends the capability of plastics into a wide range of medical device applications (*Sastri, 2010a,b,c*).

The Use of Plastic Products in Hospitals and Healthcare Systems

The most widely used plastic material in medical applications is PVC followed by PE, PP, PS, and PET. PVC most widely used in presterilized single use medical applications. It is a versatile plastic that has been used in medical applications for over 50 years (*Craftech, 2019*). In recent years, PVC has been the major plastics player in the medical market, holding about 40% share. PP came in second, with about 20%–21%. Look for PP's percentage to grow (*Plastic today, 2012*). The two main application areas in healthcare for single-use medically approved PVC compounds are flexible containers and tubing: Containers used for blood and blood components, for urine collection or for ostomy products and tubing used for blood taking and blood giving sets, catheters, heart-lung bypass sets, hemodialysis sets, etc. PVC products are used in hospitals nearly everywhere such as IV bags and tubing, examination gloves, flooring, pipes, carpet backing, wall coverings, plastic food wrap, office furniture and supplies, etc. PVC is used to make a wide variety of plastic products in hospitals, ranging from medical devices to building products to office supplies. PVC is used in both flexible and rigid applications. Most products are not labeled as PVC (*Permanente, 2005*). Medical facilities need building materials with excellent durability, chemical resistance, low maintenance costs, and affordability. The plastic material PVC, also known as vinyl, meets these demands and more. In flooring, ceiling and wall coverings, PVC reduces the need for cleaning and prevents the spread of infection with its smooth hygienic surface. Not only does it last for up to 20 years with intensive use, but PVC also offers the best value for its price. With endless design options, including signage, zone boundaries and even art, PVC makes hospitals more comfortable, energizing, and welcoming for all. As a result, hospital vinyl flooring and other PVC hospital interiors are popular throughout the world (*The European Council of Vinyl Manufacturers, 2019*).

Medical facilities need building materials with excellent durability, chemical resistance, low maintenance costs, and affordability. The plastic material PVC, also known as vinyl, meets these demands and more. In flooring, ceiling, and wall coverings **Fig. 3**, PVC reduces the need for cleaning and prevents the spread of infection with its smooth hygienic surface. As a result, hospital vinyl flooring and other PVC hospital interiors are popular throughout the world (*The European Council of Vinyl Manufacturers, 2019*).

Choosing the right floor for a hospital can be a bit of a complex endeavor. There are several factors that come into play: What room or rooms in the hospital need flooring, longevity, what is required comfort-wise underfoot, esthetics, point load and rolling load requirements, cleanability, and cost. It's important to take everything into account to make the right decision (*Continental Flooring Company, 2017*). Vinyl flooring is found in hospitals worldwide.

Fig. 3 Vinyl flooring in hospital. Reproduced from The European Council of Vinyl Manufacturers, 2019. PVC in hospital interiors. [Online] Available at: <https://pvcmed.org/healthcare/pvc-hospital-interiors/> (accessed April 2019).

Fig. 4 Operating theater lights.

This is due to a unique combination of properties that make vinyl an ideal material for healthcare facilities, such as hygienic, high durability, safe and shock-absorbent, low total cost of ownership, and providing a more welcoming hospital (**Fig. 3**). PVC wall and ceiling coverings are a favorite in many hospitals thanks to their esthetic, hygienic, and cost-effective qualities. **Fig. 4** shows operating theater lights that are safe and very easy to clean, resist hazardous substances, and are very easy to control during the operation.

Vinyl wall covering is attractive, available in grades of thickness, suited to heavy traffic, and will stand up to many years of heavy use. Also, vinyl wall and ceiling coverings are not only easy to clean, they are also easily repaired should damage occur.

PVC wall and ceiling coverings are fire-retardant, and are easily repaired should damage occur. PVC wall and ceiling coverings can be made shock-absorbent and thus can withstand collisions with beds and other types of hospital equipment. More than 40% of all plastics-based disposable medical devices used in hospitals are made from PVC (PVCMed Alliance, 2019a,b).

Plastic products in healthcare application have achieved very important results and now plastic products are everywhere, from exam gloves to IV tubes or heart valves, Plastic packaging is particularly suitable for medical applications. It safely guards against contamination. Innovations in plastics are making new procedures possible. Just think of an artificial plastic heart, of bacteria-resistant plastics, or of body parts tailored to the needs of the patient and printed in the 3D printer.

Recently, there are effective plastic products in healthcare systems such as unblocking blood vessels: In the latest heart surgery, thin tubes (catheters) are used to unblock blood vessels, while deposits obstructing them can be broken down with a tiny

Fig. 5 Catheters are used to unblock blood vessels and orthopedics device. Reproduced from Plastic Europe, Association of Plastic Manufacturers, 2016. The Plastic Industry Berlin August 2016. [Online] Available at: <https://committee.iso.org/files/live/sites/tc61/files/The%20Plastic%20Industry%20Berlin%20Aug%202016%20-%20Copy.pdf> (accessed April 2019).

spiral-shaped implant, a vessel support. Positioned in the treated artery, it is made of a plastic developed specifically for the medical field and charged with active substances. A second application is known as a prosthesis. Plastics are now being used as orthopedic devices, where they align, support, or correct deformities. Synthetic material also plays a vital role for diseased arteries that cannot be helped via vessel support. An affected section of the aorta is removed, and the gap is bridged by a flexible plastic prosthesis. Thanks to this, the body's lifeline becomes fully functional again **Fig. 5**.

Another innovation is artificial corneas: Eye injuries or chronic inflammation, for example, corneal erosion, can impair sight, and if a transplant has little chance of success, a prosthesis is the only hope. Artificial corneas made from special silicone are now available for treatment. Only 0.3–0.5 mm thick, highly transparent, flexible, and made of biomechanics like a natural cornea, it can restore clear vision again.

Also, hearing aids, one of the most important innovations for people with severely impaired hearing, can now use a plastic implant. It transforms acoustic impulses into electrical ones, bypassing the damaged cells and stimulating the auditory nerve directly (**Fig. 6**) (Plastic Europe, Association of Plastic Manufacturers, 2016).

General application of the most important types of plastic (PE, PP, PVC, PS, and PC) in medicine and medical devices and their products in hospitals and healthcare systems are illustrated in **Table 3**. In medicine and healthcare the diversity of plastics' uses is incredible, and many other sectors of society also have replaced glass, wood, and metal in several products including food packaging, clothing, and even in personal care products by plastic materials.

However, the development of plastic products has led to other disposable objects ubiquitous in hospitals such as IV bags and tubing. So, the importance of IV bags and tubing in caring for hospital patients is clear in the fact that they constitute 20%–25% of hospital waste.

Discussion and Conclusion

Properties of materials and available knowledge and technology are some of the most important factors that can help to find solutions for different healthcare patients. Plastic components have different required characteristics to develop and innovate new products to improve or solve specified medical and technical problems. Plastic components have helped healthcare patients live healthier and happier lives.

Plastic products have revolutionized a lot of industries for several different reasons to include the fact that they resist environmental degradation over time, are generally safe for human beings, are economical and widely available, and are produced with a wide variety of material properties that allow adaptation to many different applications.

According to this study interested in the role and importance of plastic products in the hospital and healthcare systems, and because of analyzing recent studies and topics in using plastic products in hospitals and healthcare systems and depending on the past studies and investigations of the plastic materials and their applications in the mentioned sectors, the following can be concluded:

- The main important innovations were in the past century with the introduction and wide adoption of plastics for many day-to-day applications in all fields.
- Using plastics and related products in a hospital is an increasing trend because of their cost-effectiveness, for their benefit in patients in simple and light tools and instruments, infection control, and wide availability.

Fig. 6 Artificial corneas and hearing aids. Reproduced from Plastic Europe, Association of Plastic Manufacturers, 2016. The Plastic Industry Berlin August 2016. [Online] Available at: <https://committee.iso.org/files/live/sites/tc61/files/The%20Plastic%20Industry%20Berlin%20Aug%202016%20-%20Copy.pdf> (accessed April 2019).

Table 3 Plastic products in hospital and healthcare systems

1	Polyethylene	Containers, packaging films, pouches, lidstock, breather patches, and headers for bags. UHMWPE is used as the wear bearing surface of hip and knee arthroplasty and total joint replacement.
2	Polypropylene	● Homopolymer: Thermoforming, slit film and oriented fibers, high clarity, syringes, and closures, sutures, drapes, and gowns. ● Random copolymer: Food, household chemicals, beauty aid products, clear containers, and hot fill applications.
3	Polyvinyl chloride (PVC)	● Impact copolymers: Film, sheet, profiles, high-pressure resistance, medical trays, and thin wall parts. ● Rigid PVC: Luer connectors and Y-sites. ● Flexible PVC: Secondary packaging, blister packs, solution containers, fluid transport tubes, drip chambers, diaphragms, pull rings, oxygen facemasks, and gloves.
4	Polystyrene	● General purpose: Diagnostic instruments and disposable laboratory ware, Petri dishes, tissue culture components, flasks, and pipettes. ● Oriented: Oriented polystyrene films can be printed and laminated to foams for food service plates and trays offering improved esthetics. The films can also be used as a laminate to polystyrene sheet for a high-gloss shine. ● High impact: Laboratory ware and other medical devices.
5	Nylon	Soft contact lenses, wound dressings, drug delivery.
6	Polycarbonate	Medical apparatus (sterilizable), reservoirs, high-pressure syringes, artery cannulas, stopcocks, luers, centrifugal force separators, blood filter housings, dialyzer housings; glucose meters, pumps, insulin pens; surgical device handles and housings.
7	Polyacrylate	Clear, disposable plastics – only glass transmits light as well; chest drainage units, medical spikes, breathing apparatus accessories, urological accessories, Y-sites, check valves, filter housings, IV adapters, IV pump housings, medical cassettes, blood handling components, and catheter accessories.
8	Hydrogel (Acrylate)	Fittings, valves, pumps, tubing.
9	Polysulfone	Medical equipment that requires repeated sterilization; fluid handling couplings/ fittings.
10	Polyetheretherketone	Reusable medical components including dental syringes and keyhole surgery devices, catheters, disposable surgical instruments.
11	Thermoplastic elastomers (e.g., TPU)	Catheters, valves, needleless syringes, surgical instruments, wound dressing and tape, shunts, drug patches, medical bags, and tubing.
12	Thermoset Elastomers	Catheters, valves, needleless syringes, surgical instruments, wound dressing and tape, shunts, drug patches, medical bags, and tubing.
13	Poly-p-xylylene (Parylene)	Applications and uses: Needles, prosthetic devices, implantable components, catheter, electrodes, stents, epidural probes, cannula assemblies.
14	Fluoropolymers (e.g., PTFE)	Fittings, valves, pumps, tubing.

Abbreviations: PTFE, Polytetrafluoroethylene; TPU, Thermoplastic polyurethane; UHMWPE, Ultra high molecular weight polyethylene.

- Plastic products continue to help scientists find desired solutions for their patients such as unblocking blood vessels, orthopedic device, artificial corneas, hearing aids, and so on.
- Further innovation can improve the quality of plastic products and meet the requirements for sterilization, safety, preservation, etc. of medical equipment used in the healthcare industry. Also, more studies and researches are needed to develop recycling methods and techniques.
- It is important to require the printing of plastic codes for products and packaging.

- Researchers in healthcare continue improve and create new substances to fit and offer newly needed properties.
- The use of plastic products in hospitals and healthcare systems is very important and necessary and this importance will continue to increase.

It is recommended that plastic products manufacturers should be committed and keep working on government and international regulations that concern use of plastic products for healthcare.

Introduction

Thermal spraying processes are well-known for improving surface properties and can be applied to any components without affecting the bulk material composition (Bolleddu *et al.*, 2014). Thermal spray coating produced by optimized process parameters can extend the service life of the components and improve the performance as well (Hadad *et al.*, 2009). Tungsten Carbide – Cobalt (WC-Co) coatings are widely used in aircraft, textile, automobile, transportation, mining and power generation industries to impede various degradation processes such as wear, corrosion and erosion (Karimi *et al.*, 1993). A proper composition of hard WC phase and Co phase results in favourable combination of high wear resistance, hardness, fracture toughness, etc. (Santana *et al.*, 2008). The WC-Co coatings with nanolevel surface finish find many applications such as main aircraft landing gear cylinders and pistons (Nuse and Falkowski, 2000; Sartwell *et al.*, 2004), diesel engine cylinder (Davis, 2004) and gloss calendar roll of printing industry (Pawlowski, 2008) and many more.

Many thermal spray techniques are available for WC-Co coating on different materials and components. High velocity oxy-fuel spraying (HVOF) technique is extensively used in many industries due to its ability to produce high quality carbide coatings. HVOF technique uses high particle velocity and it leads to the favourable coating properties such as high density, high bonding strength, hardness, etc. (Stewart *et al.*, 2000). During the coating deposition, the Co binder matrix is melted sufficiently and WC particles are dissolved into it. However, the WC particles are subjected to the severe decomposition during coating fabrication and brittle W_2C or W phase are formed around the WC particles. The W phase, free C further reacts with the Co binder and forms a brittle amorphous phase ($Co_xW_yC_z$), which degrade the intersplat bonding, in turn, the mechanical properties of the coatings (Xie *et al.*, 2013; Qiao *et al.*, 2001). Hence, sufficient melting as well as suppression of WC particles decomposition is essential to improve the properties of the coatings. The decomposition can be declined by reducing the flame temperature and exposure time of powders to the high temperature (Karimi *et al.*, 1993).

The coating deposited by thermal spray processes is very rough and not suitable for many applications. Hence, some polishing process needs to reduce the surface roughness of the coating and make it suitable for final usage. Machining and grinding are the some of the preferable processes for finishing of WC-Co coatings (Murthy *et al.*, 2001). Liu *et al.* (2002b) performed surface grinding of nanostructured WC-Co coating deposited by HVOF process. Diamond abrasive based cup-type wheel was used. Surface roughness and grinding forces are studied with the reference to the grinding process parameters. In another work nanostructured coating was finished by grinding and burnishing (Tillmann *et al.*, 2015). From the reported work, it is observed that machining, grinding and ball burnishing are not able to finish the WC-Co coatings to the nanometer scale. This is due to the severe mechanical contact by rigid abrasive tool, very high finishing forces which may result in particle pull out from the coating and low heat transfer from the finishing zone due to the inherent porosity of the coating (Tucker, 1994). Therefore, some gentle finishing process such as shape adaptive grinding (SAG) (Beaucamp *et al.*, 2015; Ghosh *et al.*, 2018) needs to be applied which does not apply very high finishing forces to achieve nanolevel surface finish.

In the recent years, many efforts are made to develop new coating material to enhance the mechanical properties of the WC-Co coating. The grain size of the coating is reduced to nm scale from micron scale and the binders are also being reinforced by some new materials like carbon nanotubes (CNT). An exhaustive research work is continuing to find more suitable fabrication technique and to optimize the process parameters. Furthermore, many post processing techniques are also used and being developed to improve the surface finish as well as surface integrity of the coatings as shown in Fig. 1. In this article, the conventional as well as newly developed coating materials and its various post processing techniques are comprehensively discussed. The mechanical and tribological properties of the newly developed material and processed surfaces are also reported.

Materials

Conventional or Microcrystalline Coating

Conventional WC-Co coatings have been extensively used since the past decades. In this case, the WC grains having size in micron scale (generally 1–20 μm) are embedded into the ductile Co matrix. The percentage of Co content may be varied (generally 10%–23%) to impart different mechanical properties. The decomposition of WC particle during fabrication can hardly be eliminated that leads to the deterioration of the interface bonding. Therefore, the tribological property of the coating is declined. Many literatures are available where the correlations among the process parameters, powder characteristics, coating microstructure and wear resistance of the coatings are studied. It is found that processing condition, initial powder characteristics (i.e., phase content, particle size and grain size) have remarkable effect on the properties of the coatings (Ramnath and Jayaraman, 1989; Voyer and Marple, 1999; Stewart *et al.*, 1999). Yang *et al.* (2003) have studied the effect of WC grain size on the wear behaviour of WC-12Co coating. Higher order decomposition of WC has been observed with the reduction in grain size. It was observed that the specific wear rate of the coatings increases with the increase of carbide grain size. Usmani *et al.* (1997) fabricated

Fig. 1 Fabrication and post processing of WC-Co coating (CNT-carbon nanotube, SAG-shape adaptive grinding, CA-SAG- chemical assisted SAG, FSP-friction stir processing).

WC-17Co coating having different carbide grain sizes. It is observed that the coating with finer grain size possess higher hardness but more prone to decomposition that leads to the lower fracture toughness and abrasion resistance. The decomposition of WC can be significantly inhibited by the addition of chromium (Cr) and it also suppresses the formation of metallic tungsten (W). Moreover, Cr improves the binding strength among the WC phases and the binder and hence, the abrasion resistance of the coating is improved (Karimi *et al.*, 1993). It is also observed that corrosion resistance of the WC-Co coating is lower than the WC-10Co-4Cr coatings owing to the electrochemical properties of cobalt itself (Guilemany *et al.*, 2005). Hence, in the recent days WC-10Co-4Cr coatings are extensively used.

Nanostructured Coating

In the past years, a remarkable progress has been made in the synthesis of nanocrystalline material. Its application has been extended into various fields of science and technology, including coatings. Nanostructured WC-Co coating has been extensively used for its enhanced mechanical properties (He and Schoenung, 2002). The grain size of WC in nanostructured WC-Co coating varies in the range of 10–500 nm. The coating with grain size below 100 nm is called as nanostructured coating and beyond 100 nm is called as near nanostructured coating (Guilemany *et al.*, 2005). Nanostructured coatings experience higher decarburization compared to the coating with micron scale grain size owing to its larger surface-to-volume ratio (Kear *et al.*, 2001; Lekatou *et al.*, 2015). Moreover, nanostructured powder suffer a higher temperature than the conventional one at same spraying parameters and that also leads to the intense decomposition of WC particles (He and Schoenung, 2002). Therefore, the interfaces between the carbides and amorphous Co increase and its characteristics have a significant role to obtain the desired coating properties. However, Stewart *et al.* (1999) have reported that nanostructured coating possesses a lower wear resistance than the conventional one owing to the severe decomposition of WC particles that leads to the reduction in volume fraction of hard WC phase and generation of amorphous phase in binder. Same observations are also made by Dent *et al.* (2002). He *et al.* (2000) performed the characterization of nanostructured WC-12%Co coating and it is observed that the fracture toughness is increased but hardness is not improved remarkably. He *et al.* (2002), Liu *et al.* (2002b) further developed near nanostructured WC-18%Co coatings with a very small amount of non-WC/Co phases. An improvement in both hardness and wear-resistance were observed.

It is also observed that the propylene gas has the ability to retard the decomposition and hence, superior quality coating can be made. Guilemany *et al.* (2005) reported 30% higher hardness of nanostructured WC-12 Co than its conventional counterpart. This is attributed to the finer size carbides distribution in the Co matrix and the hardening effect of W and C in the binder.

Guilemany *et al.* (2006) introduced bimodal WC-Co powder which is a homogeneous mixture of nano-sized and micron-sized WC-Co particles. To reduce the decarburization of WC and associated cost related to nanostructured WC-Co coating, bimodal powder is prepared where nano-sized powder is the minor constituent (approx. 30%). The cross-sectional SEM images of conventional, bimodal and nanostructured coatings are shown in Fig. 2(a–c), respectively. The micron size (1–4 μm) WC particles are heterogeneously dispersed owing to its lower melting and worse deposition as shown in Fig. 2(a). This leads to the higher porosity of conventional coating compared to others. Fig. 2(b) shows the morphology of bimodal coating. Heterogeneity is also observed in the bimodal coating as it is mixture of nanostructured (30–50 nm) and conventional particles (2–3 μm). A homogeneous dispersion of nanoscale (less than 100 nm) WC grain is observed in the nanostructured coating as shown in Fig. 2(c).

The spraying condition is not optimized for bimodal and nanostructured coating and standard spraying condition for conventional coating is used for all the coatings. Therefore, the temperature of the particles depends on its sizes. The nanostructured and bimodal coatings experience more decarburization than the conventional coating. However, the hardness of nanostructured coating is comparatively higher than the other coating. Although nanostructured coating possesses higher hardness, the wear resistance of the bimodal coating is highest. The nano-sized WC particles are dispersed between the gaps of the micron sized WC particles and strengthen the matrix and the presence of hard micron size WC particles in the bimodal coating seems to be the reason of higher wear resistance. [Aw and Tan \(2006\)](#) have also developed a bimodal WC-17Co coating by coupling the very fine nanostructured WC grains with micron-sized grains. They have also observed denser coating than its conventional counterpart.

[Mateen et al. \(2011\)](#) have developed a duplex Co coated near-nanostructured WC-Co powder to impede the decarburization of the WC. **Fig. 3** shows a schematic diagram of a normal carbide particle and a developed particle with the same composition. It is observed that the properties of the near-nanostructured coating such as hardness and wear resistance are better than the conventional one. Moreover, the fracture toughness and wear resistance of the near-nanostructured coating was improved significantly.

[Wang et al. \(2018\)](#) introduced an idea to replace some of the interfaces of WC and amorphous Co (**Fig. 4(a)**) by WC/WC boundaries through near nanostructured WC grains in the coating as shown in **Fig. 4(b)**. In this study, a mechanism of formation of a cluster structure is proposed by bonding WC grains to reduce the intergranular fracture.

In this study, grain growth inhibitors (such as VC and Cr_3C_2) are added to the WC-12 wt%Co powder to reduce the mean grain size of WC from 0.47 μm to 0.22–0.24 μm . **Fig. 5(a)** shows the SEM image of worn surface without grain growth inhibitors (GGI). It is observed that the amorphous Co binder is expelled and WC particles are revealed. Thereafter, the WC particles also get dislodged owing to the removal of binder as shown in **Fig. 5(c)**.

Fig. 5(b) shows the SEM image of worn surface with GGI. The hard WC particles are bonded to each other through the grain boundaries inside the cluster. The thickness of Co binder is significantly reduced. Although, the upper Co binder is expelled, the revealed WC particles are not dislodged owing to the strong binding effect of cluster as shown in **Fig. 5(d)**. Thus the material loss during tribological test is greatly reduced that leads to the remarkable improvement of the wear resistance of the coating.

Coating With the CNT Reinforcement

It is reported that the introduction of multi wall carbon nanotube (MWCNT) can improve the coating properties like hardness, toughness and wear resistance of the composite as well as coating (Xia *et al.*, 2004; Zeng and Lin, 2009; Esawi and Farag, 2007; Balani *et al.*, 2008; Thostenson *et al.*, 2001). This may be attributed to the fiber reinforcement. Rodríguez *et al.* (2014) introduced WC-12 wt% Co conventional coatings with the CNT reinforcement and the tribological and mechanical properties are compared with the coatings without reinforcement. In this study, 0.35 wt% of CNTs (outer diameter=20–40 nm, length=5–15 μm) were mixed with the conventional WC-12% Co powder in ethanol solution by jar-milling for different mixing times. Thereafter, the mixed powder was sprayed using HVOF technique. It is observed that coating fabricated with powder mixed during 36 h reduces porosity and increases hardness. In the case of reinforced coating a higher abrasive wear resistance is observed than the non-reinforced coating. The coating produced from 36 h of mixing possesses an abrasive resistance which is many times higher than the conventional coating as well as the nanostructured coating. This is attributed to the CNTs behaving as bridges and improving the cohesion between lamellas as shown in Fig. 6. As a result mechanical and tribological properties are improved.

Thakur and Arora (2017) developed a CNT reinforced nano-WC-CoCr coating to improve the properties of the coating. It is observed that the introduction of CNTs in the coating enhance the fracture toughness as well as erosion resistance by 'splat-bridging' feature. Moreover, it is also found that the CNT reinforcement favoured the plastic deformation by suppressing the brittle fracture in the coating material.

Fig. 6 CNTs bridge in the coating. Reproduced from Rodríguez, M.A., Gil, L., Camero, S., *et al.*, 2014. Effects of the dispersion time on the microstructure and wear resistance of WC/Co-CNTs HVOF sprayed coatings. *Surf. Coat. Technol.* 258, 38–48.

Fabrication Techniques

In the case of thermal spray coating, the coating materials mostly in the form of powder fed to the torch or gun where they are heated around its melting point. Thereafter, the molten or nearly molten droplets of material are accelerated toward the substrate. On impact, the droplets flow into thin lamellar particles and adhere to the surface. The total coating thickness is can be attained by employing multiple passes of the gun. The WC-Co coating can be obtained by various thermal spray processes such as plasma spray, detonation-gun spray, HVOF and cold spray process.

Plasma Spray

In the case of plasma spray process, the temperature of the plasma flame is very high and WC can be easily decarburized (Karimi *et al.*, 1993). Furthermore, cobalt may be evaporated during this process. The microstructure of plasma sprayed WC-Co coating possess many defects such as gas pores, high percentage of porosity, unmelted particles, poor interconnection between the solidified splats (Deen *et al.*, 2017; Afzal *et al.*, 2014, 2015). This may lead to the poorer WC-Co coating properties. Tribological properties and microstructural characterization of plasma spray of WC-Co coating are compared with other coating techniques (Zhu *et al.*, 2001; Al-Mutairi *et al.*, 2015; Sohi and Ghadami, 2010).

Detonation-Gun Spray

In detonation-gun spray process, a high velocity (800–1200 m/s) can be imparted to the spray powders (Du *et al.*, 2005). Therefore, the spraying particles experience a lower temperature and the inflight time is also reduced compared to plasma spray. This leads to the less decomposition of WC phase and hence, better coating properties like higher bond strength, density and lower porosity (Murthy *et al.*, 2001; Wang *et al.*, 2010). However, D-gun spraying may generate high residual stresses in the coating that leads to the formation of cracks (Wang *et al.*, 2010).

High Velocity Oxy-Fuel (HVOF) Spray

High velocity oxy-fuel (HVOF) spraying technique is widely accepted as a most versatile and flexible spraying process for WC-Co coating. The high particle velocities (greater than 500 m/s) and low flame temperatures (lower than 3000°C) reduce the decomposition of the WC phase and that leads to the superior quality of coating (Murthy *et al.*, 2001; Hong *et al.*, 2013). As a result, HVOF sprayed coating possesses better coating properties. The decarburization of WC phase during coating can hardly be eliminated but, it can be reduced by optimizing the process parameters (Thakur and Arora, 2017).

Cold Spray

Cold spraying or called cold gas dynamic spraying process is comparatively new thermal spray process. In this process, spray particles are accelerated to a high velocity (300–1200 m/s) using a supersonic gas flow (Ji *et al.*, 2013). The material is deposited through intensive plastic deformation upon impact at a temperature far below the melting point of spray materials. As a result, the inherent problems to most of the thermal spray process like oxidation, decomposition, etc., can be eliminated. However, the cold spray process is widely used for metallic coating and it possesses very low deposition efficiency in the case of WC-Co coating owing to the lack of ductile phase (Lekatou *et al.*, 2015; Kim *et al.*, 2005).

Post Processing Techniques

Grinding and Ball Burnishing

The as-sprayed WC-Co coating possesses very high surface roughness. The surface roughness of coatings needs to be reduced to make it suitable for end use. Grinding is well accepted and widely used process to reduce the roughness of coating to sub-micron scale from micron scale. Processing of different WC-Co coatings by grinding and major findings are mentioned in [Table 1](#).

Shape Adaptive Grinding (SAG)

Shape adaptive grinding (SAG) is a flexible polishing process where abrasive particles are supported by elastic backing ([Beaucamp et al., 2015](#)). SAG can undergo large deformation of the abrasive tool as compared to conventional grinding. [Ghosh et al. \(2018\)](#) introduced a multistep finishing strategy using conventional grinding, SAG and chemical assisted SAG (CA-SAG) to achieve nanoscale surface finish of WC-12Co coating. Zirconia-alumina polishing pads was used in SAG and CA-SAG. While, Murakami's reagent (potassium ferricyanide ($K_3[Fe(CN)_6]$), KOH and distilled water in 1:1:10 proportion) was selected as a chemical for CA-SAG ([Polini et al., 2006](#); [Peters and Cummings, 1993](#)). From the 3D surface topography of WC-Co coating before finishing, it is observed that it has very high surface unevenness ([Fig. 7\(a\)](#)). After grinding, it is reduced as shown in [Fig. 7\(b\)](#) and grinding marks were clearly visible in 3D topography which are generated by the aggressive interaction of diamond abrasive with the coated surface. SAG ([Fig. 7\(c\)](#)) and CA-SAG ([Fig. 7\(d\)](#)) were applied to reduce the areal surface roughness to nanometer level. Areal surface roughness (S_a) is reduced to 53 nm from initial 5.04 μm .

[Fig. 8\(a-d\)](#) shows the secondary electron images of the as-sprayed and further processed surfaces. Severe plastic deformation was observed on the coating when conventional grinding was used for pre-polishing. The deformed layer consists of plastically deformed and fragmented WC particles (indicated by arrows 1–2) and the relatively soft cobalt binder is smeared out evenly. Using SAG, the deformed surface layer was removed completely from the ground surface and the WC particles and Co phases were revealed. However, few grinding marks were present (indicated by arrow 3) on the surface and the WC particles were protruded slightly above from the relatively soft Co binder. It is observed in [Fig. 8\(d\)](#) that surface of WC particles and Co binders are lying in the same plane as WC was preferentially removed in the presence of Murakami's reagent. All the grinding marks were removed and the whole surface (both WC particles and Co binders) was finished uniformly. In this case also, no fracture or cracks were observed hence material removal takes place through plastic flow.

Laser Remelting of the Coating

[Chen et al. \(2005\)](#) performed laser remelting of HVOF sprayed conventional and nanostructured coating. At first, WC-12 Co coatings with micron-scale and nanoscale WC phases were deposited by HVOF technique. Thereafter, the laser remelting of the coatings is carried out using a 5 kW CO₂ laser of 2.2 kW, beam diameter of 4 mm, scanning speed of 1000 mm/min. re used and nitrogen as a shielding gas. It is observed that the porosity of the coating is reduced little bit by remelting. [Fig. 9\(a, b\)](#) shows the microstructure of as-sprayed and laser remelted coating. Some major cracks are found on the laser remelted coating as shown in [Fig. 9\(b\)](#). Furthermore, significant reduction in carbide size is also observed. The induced high thermal stress and decarburization of WC phases during remelting are responsible for the crack formation and fragmentation of carbides. It leads to the remarkable reduction in microhardness of laser remelted coating. For both type of coating, the hardness is reduced after remelting. The finer size carbides can be easily pulled out and hence, the wear rate of the laser remelted coatings is also higher than the as-sprayed coatings.

Dejun and Tianyuan ([Dejun and Tianyuan, 2017](#)) performed the laser remelting of HVOF sprayed WC-12Co coating using CO₂ laser of 800 W, scanning speed of 500 mm/min and spot size of 15 mm × 2 mm. It is found that the bonding strength of the coating with the substrate become more strong owing to the formation of metallurgical bond in addition to the mechanical bond. [Chikarakara et al. \(2010\)](#) also performed the laser treatment of WC-CoCr coating. It is observed that the higher level of irradiance resulted in poorer roughness and porous surfaces. Moreover, cracks are formed on the coating and microhardness is also reduced. The lower levels of irradiance can produce more uniform microstructures, reduce the porosity and increase the microhardness of the laser remelted coating.

Friction Stir Processing of the Coating

[Rahbar-Kelishami et al. \(2015\)](#) performed friction stir processing (FSP) of WC-12Co coating to improve its wear resistance. The FSP of the sprayed layer was carried out with a 3° tilt tool angle. The tool is made of WC-3%Co. The tool rotation of 600 rpm and the feed rate of 30 mm/min were selected as process parameters. The sliding wear resistance of the coatings was performed using a pin-on-disk type apparatus with alumina ball as a counter body. The 3D topography and 2D surface profile of wear tracks of as-sprayed and FSP processed surface are shown in [Fig. 10\(a,b\)](#), respectively. [Fig. 10\(a\)](#) shows a porous structure of the as-sprayed coating as well as in the wear track. The pits are visible in the wear track which represents the material removal during the wear test. The depth of wear track was around 21 μm . A dense structure is observed in the wear track of the FSP processed surface as shown in [Fig. 10\(b\)](#) and the depth of the wear track was around 5.2 μm . The comparison

Table 1 Grinding and ball burnishing of WC-Co coating

Authors	Coating material	Process parameters**	Major findings
Murthy <i>et al.</i> (2001)	WC-10Co-4Cr (conventional)	$V_s = 25$ m/s, $V_w = 6$ mm/s, $a_i = 10$ μ m, $a_c = 0.75$ mm Grinding fluid -Water soluble oil. Wheel-resin bonded diamond.	- Grinding induces a high compressive residual stress in the coating surface owing to the aggressive interaction of diamond abrasives with the coated surface. - The presence of high compressive residual stress increases the erosion resistance of the ground surface.
Liu <i>et al.</i> (2002b)	WC-12 Co (nanostructured)	$V_s = 33$ m/s, $V_w = 1, 4$ and 8 mm/s, $a_i = 2, 5, 15$ and 30 μ m Wheel-Cup-type diamond bond-vitrified, resin and cast iron fiber grit size-125, 15 μ m grinding fluid-Water based synthetic solution.	- The normal force increases with the increase of depth of cut or feedrate and depth of cut has more influence. - The surface roughness increases with the increase of feed rate and depth of cut. - Both brittle fracture and plastic deformation are observed on the ground surface. - Grinding marks are most significant characteristic under all conditions. - At higher MRR, more brittle fractures are found.
Maiti <i>et al.</i> (2009)	WC-CoCr (conventional)	$V_s = 30$ m/s, $V_w = 5$ mm/s, $a_i = 10$ μ m. Wheel- diamond. Grinding fluid - water soluble coolant.	- The microhardness of the ground surface is increased by 33% at a thickness of 200 μm. This attributed to the incorporation of higher compressive residual stress in the ground surface. - The abrasive wear resistance and erosive wear resistance of the ground surface are increased by 64.3% and 83.4%, respectively. - At the first stage of abrasive wear, plastic deformation and subsequent removal of binder is observed. Thereafter, the WC grains get dislodged.
Masoumi <i>et al.</i> (2014)	WC-10Co-4Cr (conventional)	$V_s = 20, 25, 30$, and 35 m/s, $V_w = 142, 273, 413$, and 550 mm/s. $a_i = 4, 10, 16$, and 22 μ m. Grinding fluid -Water soluble oil. Wheel-resin bonded diamond.	- The depth of cut has a remarkable effect on the cutting forces. - Both plastic deformation and brittle fracture are identified as material removal mechanism. - As the wheel speed increases, plastic deformation becomes the dominant removal mechanism. - At higher MRR, material is removed through brittle fracture.
Tillmann <i>et al.</i> (2015)	WC-12Co (fine powder with a carbide size of 400 nm) (Grinding (1) and ball burnishing (2))	(1) $V_s = 10$ m/s, $V_w = 3.3$ mm/s, $a_i = 10$ μ m Wheel-vitrified bonded diamond. Grain size- 91 μ m. (2) Hydrostatic ball burnishing tools of dia 6.35–12.7 mm and feed rate 83 mm/s.	- The wear resistance of the forming dies can be improved by finishing the components using grinding as well as ball burnishing. - The ground and ball burnished die possess almost same wear resistance. - In ball burnishing, material is not removed. Surface finishing is obtained by plastic deformation of the coating asperities. Hence, it is an economic process.
Zoei <i>et al.</i> (2016)	WC-10Co-4Cr	$V_s = 25, 30$, and 35 m/s, $V_w = 273, 413$, and 550 mm/s, $a_i = 4, 10$, and 16 μ m. Grinding fluid-Water soluble oil. Wheel- resin bonded diamond.	- A higher compressive residual stress is induced in ground surface. - Plastic deformation is found as the dominant removal mechanism in grinding. - The wear resistance of the ground surface is improved.

** V_w is the workpiece/table velocity or feed rate, V_s is the wheel velocity, a_i is the wheel depth of cut or infeed per pass and a_c is the cross feed per pass.

of these two wear tracks clearly indicate that the volume of material removed in the case of as-sprayed coating is many times higher than FSP processed surface.

The SEM micrographs of the wear tracks of as-sprayed and FSP processed surface are shown in Fig. 11(a,c), respectively. Some micro cracks are observed on the wear track of as-sprayed coating as indicated by the arrow in Fig. 11(b). The white region indicates the adherence of alumina to the wear track during wear test. Hence, it can be concluded the microcracking and adhesion are the dominant wear mechanism for the as-sprayed coating. The microcutting marks are visible in the wear track of FSP processed sample as shown in Fig. 11(d) that indicates wear mechanism is mostly abrasive wear.

Characterizations

As mentioned in the earlier section, WC-Co coating has substantial industrial applications for its favourable properties. To evaluate or prejudge the performance of the coating during its actual applications, it is essential to perform the various characterizations of the coating. Moreover, it is generally expected that some of the properties of the coating will be improved after post-processing and that needs to be confirmed by proper characterizations. Among the various characterizations, wear and corrosion resistance,

Fig. 7 3D topography of the coated component (a) As-sprayed ($S_a=5.04\ \mu\text{m}$), (b) Grinding ($S_a=0.615\ \mu\text{m}$), (c) SAG ($S_a=266\ \text{nm}$), (d) Chemical assisted SAG ($S_a=53\ \text{nm}$). Reproduced from Ghosh, G., Sidpara, A., Bandyopadhyay, P.P., 2018. High efficiency chemical assisted nanofinishing of HVOF sprayed WC-Co coating. *Surf. Coat. Technol.* 334, 204–214.

residual stress, fracture toughness and hardness measurements are found as essential characterizations of coating. In this section, the reported results of above mentioned characterizations for various coatings are discussed.

Wear Resistance

When the two materials are in a sliding contact, wear or material removal takes place owing to the abrasion, tribochemical reaction, adhesion and surface fatigue. The tribological properties of the coating largely depend on its microstructural properties and type of loading-contact condition (i.e., tribo-system). It is expected that the coating with a higher volume fraction of hard reinforcement phases possesses high wear resistance. Literature related to wear resistance of conventional, nanostructured coatings are presented in the [Table 2](#).

Based on the available literatures, it is perceived that at the initial stage of the sliding wear, the ductile and relatively soft Co binder between the WC phases experience an intense plastic deformation. The deformed Co binder is expelled owing to the development of high compressive stress by the counter body. Under the action of the repeated loads, the fatigue cracks are generated and propagated and that leads to the micro cracking or pull out of WC particles owing to lack of adequate support from the binder. As a result, the wear debris (i.e., Co rich fine WC particles) is formed. Few wear debris are removed and some are trapped between the contacting surfaces. These trapped debris can further degrade both the surfaces as a third body abrasive. Moreover, the debris themselves undergo fragmentation and very fine debris particles are formed consequently. As the finer particles produce less damage to the surfaces, the coating with finer grain size possesses lower wear rate. The finer particles are reattached to each other owing to its large specific surface area and a tribo-film is formed over the surface as shown in the [Fig. 12](#). The ductile and soft Co acts as binder to make a dense tribo-film and facilitates good cohesion of the particles in the film and adhesion to the underlying material. This dense tribo-film protects the surface from further degradation and reduce the initial higher wear rate to a comparatively lower steady wear rate ([Yang et al., 2003](#); [Wang et al., 2013](#); [Guilemany et al., 2001](#); [Magnani et al., 2008](#); [Qiao et al., 2001](#); [Slavin and Nerz, 1991](#)).

Corrosion Resistance

Corrosion can be defined as the deterioration of the material and its functional properties owing to the chemical and electrochemical reaction of the material with its surrounding. The physical state (i.e., solid, liquid and gas), chemical composition and temperature of the environment are significant controlling parameters. Besides, relative velocity of the solution (i.e., environment) and mechanical load (such as residual stress) have also considerable effect on corrosion. Corrosion has detrimental effect on the useful service life of the components. Hence, it is desirable that the corrosion rate of the material should be as low as possible. The corrosion behaviour of WC-Co coating is complex in nature owing to the presence of multiple phases. WC phases possess eminent wear and corrosion resistance owing to its high hardness and the chemical stability. The corrosion resistance of WC-Co coating significantly depend on the properties of binder matrix because Co phase possesses very high corrosion rate ([Neville and Hodgkiess, 1999](#);

Guilemany and De Paco, 1998; Human and Exner, 1997; Berget *et al.*, 1998). The Co binder near the interface of WC phase dissolves owing to micro-galvanic effects that lead to the further pull out of WC particles. The corrosion resistance can be improved by reducing the inter-connected porosities (Wentzel and Allen, 1997, 1995).

The corrosion behaviour of the coating can be assessed by the electrochemical measurements. The measurements are generally performed in the aerated 3.5 wt% NaCl aqueous solution. All the surfaces of the sample for electrochemical test are sealed by epoxy resin except the top surface. Only the top surface will come in contact with the solution. Electrochemical tests are performed in a three-electrode test cell. The sample is treated as working electrode, a saturated calomel electrode as reference electrode and a platinum wire as counter electrode. The test generally includes open circuit potential (OCP) and potentiodynamic polarisation measurements. OCP is performed up to a certain time to stabilize its potential. Thereafter, potentiodynamic polarisation test is

Table 2 Wear resistance of WC-Co coating

Authors	Material	Parameters	Major observations
Wang <i>et al.</i> (2013)	WC-10Co4Cr	● Reciprocating ball-on-block test. ● Zirconia ball of 9.525 mm diameter. ● 50 N load, 0.075 m/s sliding speed and 1800 s time.	● The wear resistance and mechanism of the coatings is affected by both hardness and fracture toughness. ● The presence of zirconia is found in the wear track that indicates the adhesion wear also takes place. ● Decarburisation of the coating affects the wear resistance.
Liu <i>et al.</i> (2002a)	WC-18Co	● Ball-on-disk test. ● Silicon nitride ball. ● 9.8 N load, 30 m/s sliding velocity, 12,000 m sliding distance and 480,000 rotations of the disk.	● Excessive decarburization makes the coating brittle that leads to the higher wear rate. ● The existence of large pits on the wear track indicates that wear occurs mostly owing to the cleavage of the splat boundaries. ● The presence of residual cracks at the splat boundaries of as-sprayed coating increase the wear rate.
Shipway <i>et al.</i> (2005)	WC-12 Co Conventional and nanostructured	● The ball-on-disk test. ● 5000 m sliding, 0.5 m/s sliding speed and 28 mm wear track diameter. ● Alumina ball of 9.6 mm diameter.	● The wear rate of nanostructured coating is many times higher than the conventional coating. ● A few carbide cracking, pull out of WC particles and subsurface cracking are observed in the case of conventional coating. ● Considerable pitting, delamination, intense cracking on the wear track and deep subsurface cracking are found for nanostructured coating. The cracks are formed at the highly decomposed region.
Guilemany <i>et al.</i> (2005)	conventional and nanostructured WC-Co	● Ball-on-disk test. ● 131 rpm velocity, 1000 m testing distance. ● WC-Co ball with 16 mm diameter.	● The friction coefficient of conventional coating is higher than the nanostructured coating. ● The width of the wear tracks of conventional coating was 450–250 μm for the nanostructured coating. ● In spite of having more W_2C phase, higher microhardness leads to the greater wear resistance of the nanostructured coating.
Yuan <i>et al.</i> (2016)	WC-Co with the addition of submicron size WC particles	● Reciprocating wear test. ● 5 mm amplitude, 5 Hz reciprocating frequency, 33 min time, 100 m sliding distance and 5–15 N loads.	● The addition of sub-micron sized WC particles increase both the hardness and wear resistance. ● The addition of submicron size particle transforms the wear mechanism to carbide phase removal instead of splat removal. ● The bonding strength among the splats has significant effect on wear resistance of the coating.
Jacobs <i>et al.</i> (1999)	WC-Co-Cr and WC-Co	● Pin-on-disk test. ● 49 N load, 0.46 m/s linear speed, 28–45 mm track diameter and speed of 313–194 rpm.	● The wear of WC-Co-Cr coatings is mostly three-body abrasion and adhesive wear. ● The softness of Co binder impedes the three body wear in the case of WC-Co coating. The wear particles are smeared over the wear track.
Hong <i>et al.</i> (2014)	WC-10Co4Cr Nanostructured	● Corundum ball of 10 mm diameter. ● Pin-on-disk test. ● 1500 m sliding distance 70 N load and 0.9 m/s sliding velocity.	● The wear resistance of the nanostructured coating can be significantly increased by the optimizing the spray parameters. ● The removal of Co binder followed by the WC particles is observed. The cracks are initiated from the interface of binder and carbides.
Barletta <i>et al.</i> (2010)	WC-CoCr	● Ball-on-disk test. ● 10 N normal load, 0.20 m/s sliding speed and 5000 m sliding distance. ● WC-6%Co balls of 3 mm diameter.	● The wear rate falls on mild wear regime. ● It is observed that the wear resistance increases with the number of torch scan.

performed at fixed scanning rate. The corrosion potential and corrosion current density are evaluated by intersection point of anodic and cathodic polarisation curves. Some reported work related to corrosion study of WC-Co and their main finding are summarized in [Table 3](#).

Residual Stress by X-ray Diffraction (XRD)

X-ray diffraction (XRD) technique using $\sin^2\psi$ method is extensively used for the measurement of the residual stress of the coating. Residual stresses in the thermal spray coating may be compressive and tensile in nature. Compressive residual stress improves the

Fig. 12 Cross-section of the wear track. Reproduced from Yang, Q., Senda, T. and Ohmori, A., 2003. Effect of carbide grain size on microstructure and sliding wear behavior of HVOF-sprayed WC–12% Co coatings. *Wear* 254 (1–2), 23–34.

Table 3 Corrosion resistance of WC-Co coating

Authors	Material	Parameters	Major observations
Wang <i>et al.</i> (2013)	WC-10Co4Cr	- Exposed area was 1 cm². - Scanning speed was 0.5 mv/s. 3.5 wt% NaCl solution	- Various cavities or micro-pits are observed owing to the dislodgement of WC phase. - The passive oxide films of CoO, WO₃, etc., are formed and resist further corrosion of the coating.
Hong <i>et al.</i> (2013)	WC-10Co4Cr (Nanostructured)	3.5 wt% NaCl aqueous solution. - Scanning speed was 1 mv/s.	- The presence of nanoclusters and amorphous phase improve the coating corrosion resistance. - The presence of Cr leads to the formation of oxide film and retard further degradation.
Perry <i>et al.</i> (2002)	WC-Co-Cr and WC-Co	- Scanning speed was 0.25 mv/s. - Artificial seawater was used for the test.	- The matrix of WC-Co coating experiences more severe corrosive attack than the WC-Co-Cr coating. - Co matrix possesses more electronegativity than the CoCr matrix that leads to the more intense micro-galvanic corrosion in the case of WC-Co coating.
Guilemany <i>et al.</i> (2006)	WC-Co Conventional and nanostructured	3.4% NaCl solution was used. - Exposed area was 1 cm².	- The nanostructured and bimodal coating possess better corrosion resistance than the conventional one. - The presence of more amorphous phase in the nanostructured coating leads to the better corrosion resistance.

fatigue resistance of the coating. Besides, the tensile residual stress may cause cracking and lead to the fatigue failure (Matejcek and Sampath, 2001). The peening stress, thermal mismatch stress and quenching stress are the responsible to induce residual stress in the HVOF sprayed coating. In HVOF spraying, the semi-molten particles with a very high velocity strike to the substrate and that leads to the formation of peening stress which is compressive in nature. The temperature of the spray particles is rapidly dropped down to the substrate temperature from its melting point. This fast cooling rate during solidification is responsible for the generation of quenching stress and which is always tensile in nature. Moreover, the substrate and coating possess different coefficient of thermal expansion and that leads to the formation of thermal mismatch stress. This stress may be compressive and tensile in nature. However, it is observed that the peening stress and thermal mismatch stresses have dominant effect on the HVOF sprayed WC-Co coating and hence, it possesses residual compressive stress (Lyphout *et al.*, 2008; Takeuchi *et al.*, 1990; Bansal *et al.*, 2007). It is observed that the grinding of WC-Co coating induces high compressive residual stress which may leads to high hardness as well as wear resistance (Murthy *et al.*, 2001; Maiti *et al.*, 2009; Masoumi *et al.*, 2014). Literature related to residual stress measurement and major observations are mentioned in Table 4.

Hardness and Fracture Toughness

Hardness and fracture toughness have significant effect on the wear resistance and failure of WC-Co coatings. Hardness of the coating determines the penetration depth of hard particles when they are in contact. An increase in hardness of the coating indicates higher abrasion resistance. Fracture toughness determine the critical load necessary to propagate a crack in the coating. Hence, it is expected that the coating with higher hardness and fracture toughness leads to higher abrasion resistance. Besides, the size distribution of hard WC has also significant effect on wear behaviour. Hardness and fracture toughness measurement related literature is summarized in Table 5.

Table 4 Residual stress by X-ray diffraction (XRD)

Authors	Material	Parameters	Major observations
Oladijo <i>et al.</i> (2012)	WC-17Co	• X-ray diffraction using Co-Kα radiation having wavelength of 1.79 Å (7 keV). • The shift of the WC (202) Bragg peak was observed at $2\theta = 143.69^\circ$.	• The residual stress of sprayed coating on to three substrates is studied. • The radiation can penetrate up to 4 μm. • The residual stress in brass and aluminium substrates are compressive in nature. In case of super-invar, tensile stress is found.
Nourouzi <i>et al.</i> (2014)	WC-12Co	• Cu-Kα radiation was used. • The strains were evaluated using peak position ($2\theta = 98.7$) of WC in (112) reflection.	• Influences of the process parameters on the residual stress are evaluated. • Stand of distance has significant effect on residual stress followed by oxygen flow and fuel flow.
Zoei <i>et al.</i> (2016)	WC-CoCr	• Cu Kα radiation was used. • Different peak positioning techniques are used.	• Residual stress can be controlled by oxygen and fuel ratio. • The parabolic method is used for the peak positioning as it shows more accurate result. • The compressive residual stress increases after performing grinding operation.
Murthy <i>et al.</i> (2001)	WC-CoCr	• Cr Kα radiation is used. • The Bragg reflection (from WC) utilized for the measurement was from the (256) plane.	• The induced residual stress increases with the increase of depth of cut and feed rate and decrease with the speed. • High compressive residual stress is found after grinding owing to the aggressive interaction of diamond abrasives with the coating. • This attributed to the increase of micro hardness and erosion resistance of the coating.

Summary

WC-Co coating has many industrial applications as it possesses exceptional tribological as well as mechanical properties. The conventional WC-Co coatings have been widely used since past few decades. However, in the recent years, the conventional WC-Co coatings are being replaced by the nanostructured WC-Co coating. Nanostructured coatings possess better mechanical and tribological properties than its conventional counterparts. Although, there is a serious issue of higher decarburization of nano-sized WC grains during deposition, it can be impeded by optimizing the spraying parameters. The use of bimodal or duplex Co coated powder particles can also improve the coating properties by reducing the decomposition of WC phase. Furthermore, the addition of grain growth inhibitors (such as VC and Cr₃C₂) with the fine powder material leads to the formation of WC grain cluster through the grain boundaries. The wear resistance of the coating is significantly enhanced as the WC grains are strongly bonded and the possibility of grain dislodgement is reduced. The wear resistance of the coating can be significantly improved by MWCNT reinforcement. This is attributed to the CNTs acting as bridges and improving the cohesion between lamellas. Among various fabrication techniques, HVOF spraying technique proves itself as the best process for the economical deposition of WC-Co coating. Although, cold spray process has also ability to produce a superior quality of coating, it possesses very low deposition efficiency in the case of WC-Co coating owing to the lack of ductile phase. The as-sprayed coatings possess very high surface roughness and surface grinding with diamond wheel is widely used to reduce the roughness to sub-micron level. During grinding, high compressive residual stress is induced into the coating surface and that leads to the enhancement of both the microhardness as well as wear resistance. However, to attain nanolevel surface finish of the coating, more gentle and flexible finishing process is

needed. By performing SAG and CA-SAG, sequentially nanolevel surface finish can be achieved. Laser remelted coatings possess low microhardness and wear resistance owing to the crack formation and reduction of carbide size during the remelting. However, the recent study suggest that the lower levels of irradiance can produce more uniform microstructures, reduces porosity and increases microhardness of the laser remelted coating. FSP processed coatings possess better wear resistance. There is a significant lack of literature in finishing of the coating, though nanofinished coatings have significant applications. More emphasis is given to produce different coating material as well as post processing techniques to improve the coating properties as well as surface topography to make them more sustainable and suitable for different applications.

Introduction

In a wide range of fields like electric utility boilers, industrial boilers and kilns, coal is required for heat generation (Tillman and Harding, 2004) which leads to the emission of greenhouse gases (GHG) e.g., NO_x, SO_x and CO₂ (Tripathy *et al.*, 2017). Coal combustion contributes around 41.2% in total global carbon emission (Raghuvanshi *et al.*, 2006; Wu *et al.*, 2015a). Hence, alternate energy sources are being sought in order to meet energy demands and the Kyoto Protocol (Shearer, 2014; Tkaczewska and Małolepszy, 2009).

Co-firing is an emerging method in which the alternate energy options (biomass/non-conventional energy resources) is blended with coal and co-combusted. The inclusion of each ton of biomass reduces one ton of CO₂ emissions (Demirbaş, 2003). In comparison with the pure coal combustion, co-firing reduces the GHG emission as well as the cost associated with it (Doshi *et al.*, 2009; Hein and Bemtgen, 1998; Ipatti, 1988; Senneca, 2008; Wang *et al.*, 2008). Hence, due to its cost-effective and sustainable features, cofiring is gaining popularity among the industries. Countries like Denmark, United States and the United Kingdom have even made biomass inclusion compulsory in the case of electric utilities (Narayanan and Natarajan, 2007). The EU has increased the share of the biomass content from 7.5% (2010) to 14% (2020) in the co-firing process (Kalembkiewicz and Chmielarz, 2012).

Co-fired blended fly ash (CFBA) is a by-product obtained from the co-firing process. Altogether, the above-stated statistics suggest it will lead to increase in the CFBA generation (Kalembkiewicz and Chmielarz, 2012). CFBA generation is of environmental concern as it is different from conventional coal fly ash (CFA) due to the different origin of the secondary fuel and hence, restricts its use in a similar way as CFA (Fuller *et al.*, 2015; Sarabèr, 2012). In the absence of utilization route, CFBA will end up as a landfill which will be a cause of solid waste accumulation.

For the past five decades, CFA was used in the development of various construction material (Doshi *et al.*, 2009; Bouzoubaa *et al.*, 1999; Manz, 1997). Whereas, CFBA is comparatively new and its engineering properties have not been fully explored (Faleschini *et al.*, 2015; Wu *et al.*, 2011). Through literature survey of last two decades, it was observed that the various R&D work was carried out to investigate the effect of co-combustion in greenhouse gases emission trend, chemical and physical characterization of the CFBA generated and the feasibility of CFBA as a construction material. These articles provide the information regarding the available test methods for the characterization of raw material prior to be used in the concrete/mortar, fresh concrete properties and durability of concrete.

The aim of this article is to highlight the research work carried out using different kinds of CFBA as a construction material. Initial section discusses the types of co-firing and available alternate renewable fuels which was used as a secondary fuel for co-combustion with coal. In the proceeding sections, impact of co-firing on chemical (elemental composition, loss on ignition, leaching of metals, radioactivity test), physical (morphology, grain size distribution, bulk density, particle density, specific gravity, activity index) and mineralogical properties of CFBA is discussed. The study was further extended to the effect of CFBA inclusion, as a supplementary cementitious material (SCM), on the concrete/mortar properties. The mortar/concrete properties studied were, fresh concrete properties (hydration kinetics, workability, setting time), hardened concrete properties (compressive strength, water absorbability, resistance against wetting/drying cycles, freezing and thawing, alkali-silica reaction expansion, chemical tests).

Co-Combustion Fuels

Co-firing can be categorized into three types, mainly direct co-firing, indirect co-firing and parallel co-firing. In the process of direct co-firing, biomass and coal are mixed and fed into the furnace and co-combusted. Whereas, in the remaining two methods the fuels do not interact with each other during combustion (Nussbaumer, 2003). Indirect and parallel co-firing generates separate ashes of biomass and coal, whereas the co-fired blended ash (CFBA) obtained from direct co-firing is of hybrid nature, which is focussed in the present study (Narayanan and Natarajan, 2007; Kalembkiewicz and Chmielarz, 2012; Uson *et al.*, 2013). There is a vast variety of biomass type which can be used as a secondary fuel in combination with coal. Saraber (2014), has classified the available biomass which is represented in Table 1.

The number of fuel blends has been reported in the literature (Narayanan and Natarajan, 2007; Fuller *et al.*, 2015; Faleschini *et al.*, 2015; Nussbaumer, 2003; Sarabèr, 2014; Barbosa *et al.*, 2011; Cenni *et al.*, 2001; Grammelis *et al.*, 2006a; Illikainen *et al.*, 2014; Izquierdo *et al.*, 2008; Kosior-Kazberuk, 2013; Shearer *et al.*, 2010; Tkaczewska *et al.*, 2012; Wang, 2014a; Wu *et al.*, 2015b). Table 2 enlists different CFBA, which has been used as an SCM in mortar/concrete to check the feasibility of CFBA as a construction material.

Table 1 Classification of secondary fuel

S. No.	Classification of biomass	Example
1	Wood and woody biomass	Wood pellets, wood waste from commercial logging, harvesting and mill residues
2	Herbaceous and agricultural biomass	Straw, grass, maize and leaves, olive residue, cacao husks and rice husks.
3	Aquatic biomass	Algae
4	Biomass from animal origin	Manure and meat and bone meal
5	Biomass contaminated with mineral matter from anthropogenic origin	Sewage sludge, paper sludge, solid recovered fuel (SRF) and demolition wood.

Note: Reproduced from Sarab  r, A.J., 2014. Co-combustion and its impact on fly ash quality; Full-scale experiments. Fuel Processing Technology 128, 68–82.

Influence of Co-Firing on Ash Properties

CFBA composition and structure are affected by biomass type, biomass property, the proportion of the blend and the combustion conditions (Kalembkiewicz and Chmielarz, 2012; Korpil  rvi *et al.*, 2012; Shearer *et al.*, 2011). To use CFBA as an SCM, it is necessary to characterize its chemical and physical properties. From the literature review, it was observed that there is a lack of availability of the standard codes which lays guidelines specifically for the CFBA or addresses the CFBA. ASTM C 618 prohibits the use of ash in the concrete derived from other than class C and F coals (Wang, 2014a). For concrete production, Indian standard code (IS 3812: 2003) provides standard guidelines for ash obtained from coal. Whereas, EN 450-1:2009 allows fly ash obtained from co-combustion, where the biomass proportion does not exceed 10% of the total blend (Kosior-Kazberuk, 2013). Hence, in order to check the application of CFBA as a construction material, the properties of the CFBA can be compared to the limits set by standard codes for CFA (Korpil  rvi *et al.*, 2012).

Chemical Characterization

To check the feasibility of CFBA in concrete, its chemical, physical and mineralogical characterization is required (Sarab  r, 2012). For the evaluation of the same, various required test methods are enlisted in Table 3. Up to certain limits, an inclusion of biomass does not negatively impact the chemical properties of the CFBA. However, limitations in the chemical properties given in standards need to be specified minutely as some elements present in CFBA in higher quantity, are absent in coal ashes (e.g., phosphorous content, in the case of sewage sludge inclusion as a secondary fuel) (Cenni *et al.*, 2001). Combustion temperature, combustion technology and fuel used plays a major role in the mineralogy and physical properties of the fly ash (Grammelis *et al.*, 2006a; Izquierdo *et al.*, 2008; Koukoulzas *et al.*, 2009).

Elemental composition

Table 4 illustrates the elemental composition of CFBA reported in the literature. From the Table 4, it can be inferred that inclusion of 80% wood pellets did not significantly change the fly ash composition due to its lower ash content i.e., 0.02%–0.5% by weight in comparison with lignite coal, which is 10% by weight (Johnson *et al.*, 2010). Altogether aluminum, silica, potassium and sodium were found to be lesser, whereas, calcium and magnesium content was comparatively higher (Tkaczewska and Ma  lepsz, 2009). Co-combustion results in the ash containing lesser unburned carbon, alkali, magnesium oxide, chlorine and sulfate than CFA (Cenni *et al.*, 2001).

Loss on ignition (LOI)

LOI represents unburnt carbon in the ash (Kalembkiewicz and Chmielarz, 2012) and high LOI value compromises mortar and concrete strength (Sarab  r, 2014). Unburnt particles affect activity index, adsorption of air entrainment additives and workability of the mortar due to their water absorption property (Sarab  r, 2012, 2014; Kosior-Kazberuk, 2013; Foner *et al.*, 1999). Combustion temperature, particle size and moisture content of fuel plays a major role in the LOI value of the ash (Kalembkiewicz and Chmielarz, 2012; Koukoulzas *et al.*, 2009). No linear relation was observed between LOI value and biomass content in the blend (Table 4) which is affirmed by Shearer *et al.* (2011). However, the increasing trend of LOI was observed within the same biomass species. For e.g., LOI value of 15% wood pellets was 0.4, which increased to 0.9 when the wood pellet content was increased to 66% and the same trend was observed in the case of switchgrass.

Leaching of metals

Construction materials have a tendency to leach out environment polluting agents when comes into contact with water (Shaub, 1997; Heasman *et al.*, 1997). Leaching properties of the CFBA was paid less attention (Lopes *et al.*, 2003; Lapa *et al.*, 2007; Steenari and Lindqvist, 1999). Leaching property mainly depends on the composition of the feed fuel (Izquierdo *et al.*, 2008). The inclusion of olive stone and olive pulp, wood pellets and palm pit scales (Table 5) did not cause a marginal difference in leachable elements. Whereas, the inclusion of sewage sludge resulted in the higher amount of Pb, Cu, Zn, P and Sb (Izquierdo *et al.*, 2008). In the study (Grammelis *et al.*, 2006a,b), TCLP was used in the determination of 2 non-metals and 17 metals of CFBA. The inclusion of 19% olive kernels did not cause any alteration in the mobility of elements viz., Sn, Pb, As, Se, Cd and Ag. With the

Table 2 Supplementary fuel used in combination with coal reported in literature

Source	Primary fuel	Secondary fuel	Application (Mortar/Concrete)	Cement replacement (%)	Aim of the study

increase in the biomass content, the elements Ca and Cr projected a decrease in the leachability. Whereas, elements Si, Ni, Zn, Na, Fe, Cu, Al, Mg, Co and K showed higher leachability with an increase in the higher content of the biomass in the blend. These data suggest that the biomass type and its proportion in the blend plays a major role in the leachability of metals which is found to be in conformance with the statement of *Izquierdo et al. (2008)*.

Radioactivity test

Ash may contain radioactive isotopes such as ²³²Th, ²²²Rn, ²³⁸U, ²²⁶Ra (*Grammelis et al., 2006a,b*). Hence, the radioactive test is required when the ash is used in building materials (*Kalembkiewicz and Chmielarz, 2012*). Three different CFBA were subjected to radioactive tests in the studies conducted by *Grammelis et al. (2006a,b)*. It was observed that the activity of ²³²Th and ²²⁶Ra of CFBA (coal (70%) and biomass (peat 30%)) was 89 and 163 Bq/kg respectively, and the activity for the same was noted as 68 and 123 Bq/kg respectively for CFBA containing coal (50%) and biomass (50%). The activity values for ²³²Th and ²²⁶Ra further decreased to 57 and 140 Bq/kg when the CFBA was obtained from 90% wood content in the fuel mix. It was inferred that the increase in the share of biomass resulted in a decrease of the radioactivity of the ash.

Activity index (AI)

Pozzolanic activity index or activity index (AI) is the measure of the pozzolanic behavior of the ash when used as an SCM (*Sarabèr, 2012*). AI can be defined as the percentage gain in strength of ash mortar (25% cement replacement by ash) in comparison with the standard mortar at the age of 28 and 90 days. As per the EN 450-1, the AI of the ash mortar at the age of 28 and 90 days should be more than 75% and 85% of the cement mortar respectively (*Fuller et al., 2015; Sarabèr, 2012; Kosior-Kazberuk, 2013*). AI does not give information on the role of the ash behavior when used in concrete. Whereas, through this property, use of ash in the lower strength works such as masonry, road repair etc. can be ascertained (*Fuller et al., 2015*).

CFBA containing poultry dung and demolition wood fulfilled AI criteria. At the age of 28 and 91 days, AI was 82% and 90% for CFBA (18% SRF), 76% and 85% for the CFBA (33% SRF). An increase in the SRF content in the coal blend decreased AI

(Sarabèr, 2012). CFBA achieved higher AI of 102% and 107% at 28 and 90 days respectively (Kosior-Kazberuk, 2013). The coarser particle size of the CFBA resulted in the lower AI of 13% and hence, suitable as the microfiller instead of SCM (Tkaczewska and Małolepszy, 2009). It can be stated that the particle size of the ash has a major influence on the AI.

Physical Characterization

Ash can be used in concrete in the form of aggregates or binder. In order to be used as aggregates, ash should possess appropriate gradation and in a case of the binder, it should contain pozzolanic properties (Izquierdo *et al.*, 2008). Major physical characteristics are discussed in the below section which needs to be studied, prior to be used in concrete.

Morphology

Morphology of ash can be determined using Scanning electron microscopy (SEM). With the help of SEM, shape and size of grains can be studied. SEM EDX/EDS method provides the location of elements in the ash area subjected to scanning (Koukouzas *et al.*, 2009; Johnson *et al.*, 2010). CFA particles are spherical in shape (Sarabèr, 2014). As per Grammelis *et al.* (2006a,b), CFBA particles majorly consisted of the irregular periphery and the rest were of spherical, elongated and rectangular in shape. The similar kind of morphology was observed by Kosior-Kazberuk (2013). CFBA possessed sub-angular particle shape in comparison with CFA (Koukouzas *et al.*, 2009). Whereas, CFBA particles were found to be spherical in shape as per Faleschini *et al.* (2015). Mixed morphology was observed in CFBA, i.e., long fibrous wood particles along with a glass sphere (Shearer *et al.*, 2011). CFBA was found less spherical and glassy in comparison with the CFA (Tkaczewska and Małolepszy, 2009). In the described investigations, morphological characteristics of the coal ash and biomass ash both have been simultaneously observed in CFBA. Therefore, it is evident that the co-combustion of biomass with coal results in the mixed morphology of the ash.

Grain size distribution

High surface area, high fineness and low particle size are the requirements to achieve pozzolanic activity within the material (Chindaprasirt *et al.*, 2004) as well as for the proper packing within the matrix (Faleschini *et al.*, 2015). Sarabèr (2012), compared the grain size distribution of coal fly ash and two other CFBA samples. It was found that all the three samples showed similar kind of grain size distribution i.e., 4, 14 and 69 µm respectively for D₁₀, D₅₀ and D₉₀. The study (Wolski *et al.*, 2004), implemented that the sampling position also alters particle size. Mean particle size of CFBA (15% sewage sludge) collected at different sections i.e., filter, cyclone and air pre-heater were found to be less than 10 µm, 2–10 µm and 10–200 µm respectively. Smaller particle size of

CFBA was found i.e., 35% of the fly ash particles were less than 10 μm size (Faleschini *et al.*, 2015). The CFBA (15% wood pellets) consisted majorly of particle size greater than 50 μm , whereas CFBA (66% wood pellets) showed the particle size same as the coal fly ash i.e., 14 μm (Johnson *et al.*, 2010). From these values, it was concluded that the variation in the particle size was dominated by the factors combustion conditions (temperature, loading, soot blowers, etc.) rather than the composition of the fuel which is also affirmed by Johnson *et al.* (2010).

Specific gravity

The specific gravity of CFA is in the range of 2.15–2.63 g/cm^3 (Shearer, 2014; Johnson *et al.*, 2010). Whereas for two CFBA (15% biomass, 66% biomass), the obtained specific gravity was 2.361 ± 0.036 and 2.587 ± 0.064 g/cm^3 respectively (Johnson *et al.*, 2010). Eight different CFBA were evaluated for specific gravity, which was found to be 2.20–2.48 g/cm^3 (Shearer, 2014). These values affirm the statement given by Shearer (2014), i.e., the biomass co-combustion with coal does not cause a significant difference in the specific gravity.

Mineralogical Characterization

The nature of macro elements present in the fly ash is estimated through the mineralogical characterization (Sarabèr, 2012). With the help of Qualitative X-ray diffraction (XRD) mineral phases which are present in the ash can be identified (Faleschini *et al.*, 2015; Koukouzas *et al.*, 2009; Jenkins and Snyder, 1996). However, in order to know the percentage of these available mineral phases Quantitative X-ray diffraction (XRD) (e.g., Rietveld's method) is required (Sarabèr, 2012; Koukouzas *et al.*, 2009). Coal fly ash consists of various phases mainly crystalline phases (e.g., mullite and quartz), amorphous (unburnt particles) and glass phase (Koukouzas *et al.*, 2009; Lothenbach *et al.*, 2011; Ball and Carroll, 1999), no matter whether the coal is mono-combusted or co-combusted (Grammelis *et al.*, 2006a).

Minerals which are majorly present in CFA were found to be Quartz (SiO_2), Anhydrite (CaSO_4), Hematite (Fe_2O_3), Illite ($\text{K}_2\text{H}_3\text{O}$) ($\text{Al,Mg,Fe}_2(\text{Si,Al})_4\text{O}_{10}[(\text{OH})_2,\text{H}_2\text{O}]$), Calcite (CaCO_3), Mullite ($\text{Al}_6\text{Si}_2\text{O}_{13}$), Magnetite (Fe_3O_4), Amorphous material (Koukouzas *et al.*, 2009; Font *et al.*, 2010). Out of the enlisted CFBA in Table 2, common mineral observed in CFA and CFBA were quartz (SiO_2), hematite (Fe_2O_3) and mullite ($\text{Al}_6\text{Si}_2\text{O}_{13}$). In addition to these, Sillimanite (Al_2SiO_5) was observed in CFBA (Faleschini *et al.*, 2015). Amorphous phase was found to a large extent in the coal fly ash and two CFBA samples. Minerals observed in all the samples were quartz (SiO_2), periclase (MgO) and in very less amount of anorthite ($(\text{Ca,Na})(\text{Al,Si})_2\text{Si}_2\text{O}_8$), anhydrite (CaSO_4), calcite (CaCO_3), belite (Ca_2SiO_4), gehlenite ($\text{Ca}_2\text{Al}_2\text{SiO}_7$), feldspar ($\text{K}_{0.5}\text{Na}_{0.5}\text{AlSi}_3\text{O}_8$), mullite ($\text{Al}_{4.54}\text{Si}_{1.46}\text{O}_{9.73}$), lime (CaO), hematite (Fe_2O_3). Both CFBA samples possessed similar kind of mineralogy as coal fly ash (Johnson *et al.*, 2010). Crystalline phase observed in the CFA were quartz and mullite. In addition to these two phases, free lime and periclase were present in the CFBA (Tkaczewska and Małolepszy, 2009). As per Koukouzas *et al.* (2009), the elemental composition of the fuel is responsible for the minerals found in the ash. For example, anhydrite is a mineral which is found in the ash when calcium is present in the fuel. Hence, CFBA (obtained from either combustion of wood chips or co-combustion of wood chips and coal) possessed was rich in anhydrite due to the presence of calcium in coal and wood chips. Literature survey implements that the mineralogy depends on the composition of the fuel. In all the cases, the minerals which are due to the coal were found common. Whereas, the variation in the mineralogy was majorly due to the composition of the biomass included in co-combustion.

Fresh Concrete Properties

Hydration Kinetics

Mortars were prepared with and without cement replacement as per the standard ASTM C 109 with the proportion 1:2.75 (cement: sand) and $w/c=0.485$. The heat of hydration in mortars consisting of 25% ash as an SCM was observed to be approximately 19% lesser in comparison with the control mortars (Shearer *et al.*, 2011). An experimental study was carried out in order to compare the heat evolved at 24 h and 72 h in the cement mortars. Different types of mortars were cast as control mix (with no cement replacement), with 20% and 40% cement replacement by CFA and with 20% and 40% cement replacement by CFBA. Heat evolution in 20% CFBA replacement at 24 h was 132 kJ/kg and at 72 h was 171 kJ/kg which is 20% less than the control mix. When the same is compared with the specimens with 20% CFA replacement, the heat evolution in the CFBA mortars was found to be 14% and 17% lesser at the end of 24 h and 72 h. The heat of evolution further reduced to 110 kJ/kg and 139 kJ/kg at 24 h and 72 h respectively when the replacement ratio increased to 40% of cement by mass (Tkaczewska and Małolepszy, 2009). It is concluded in the studies that the pozzolanic substitution resulted in the less availability of cement for the hydration and the inert behavior of the CFBA in the initial stages of hydration reaction lead to the decrease in the heat of hydration.

Workability

Factors such as fineness, morphology, LOI, particle size distribution, water demand affect the workability of mixtures (containing ash and cement) (Paya *et al.*, 1996). CFBA inclusion reduced workability up to 50%. Whereas, CFBA (obtained from co-combustion of higher percentages of the biomass with coal) projected the least reduction in the workability, which suggested that the

CFBA does not necessarily have a negative impact on the workability. The angular shape of particles of wood ash did not affect the workability and was stated that the properties like reduced particle size and LOI may be prevailing factors (Shearer *et al.*, 2011). In the experimental study (Johnson *et al.*, 2010), for a particular flow, water demand reduced with the increase in the percentage replacement of cement by CFBA. Hence, it is inferred that the workability is independent of kind of ash and majorly dominated by the physical parameters of the ash, which affirms the statement given by Paya *et al.* (1996).

Setting Time

Setting time of cement mortars prepared by replacing 25% of the cement by the CFBA was tested as per the EN 450-1. Initial and final setting time of the control mix was found to be 271 and 388 min respectively. Initial setting time of the CFBA with 50% poultry dung (PD), 30% demolition wood (DW), 18% solid recovered fuel (SRF1) and 39% solid recovered fuel (SRF2) observed to be 283, 290, 297 and 405 minutes respectively. While the final setting time for the same was observed as 396, 459, 477 and 557 min respectively. Values suggest that there is no co-relation between the setting time and the biomass type in the blend. Whereas, in the case of SRF, the increase in the biomass share in the blend results in a increase in the initial and final setting time with respect to control mix (Sarabèr, 2012). Setting time of plain cement mortar and three types of mortars with 25% replacement (% weight by mass) by CFA, CFBA (4% biomass) and CFBA (8% biomass) was studied. The initial setting of the mortars with and without replacement was found to be similar and the final setting was 6.25 h for all (Shearer *et al.*, 2011).

Mechanical Properties of Hardened Concrete

Above described properties of the material is important to know about the material behavior, when used in concrete. The inclusion of fly ash causes an alteration in the microstructure of the cement matrix (Tkaczewska and Małolepszy, 2009; Wang *et al.*, 2008; Pigeon *et al.*, 1996). The performance of CFBA in concrete is complex (Sami *et al.*, 2001). In order to achieve satisfactory concrete performance, it is mandatory to check the feasibility of concrete composites to sustain environmental exposure (Kosior-Kazberuk, 2013). In this section, physico-mechanical tests performed on concrete (containing CFBA) is discussed.

Compressive Strength

CFBA was used as a partial replacement of Portland cement in the production of concrete. Cement replacement was varied from 0%, 5%, 15% and 25% with a constant w/c ratio of 0.5. Compressive strength at the age of 28 days for 0%, 5%, 15% and 25% was 59.7, 52.2, 49.1 and 45.2 MPa respectively. With the increase in the CFBA %, compressive strength declined as well as initial strength gain was observed to be at a slower rate (Kosior-Kazberuk, 2013). CFBA was also used as an SCM in concrete and the mechanical properties were compared to the control mix and concrete with CFA (20% by volume) with $w/c \leq 0.5$. Compressive strength observed at the age of 28-days were 40.7, 38.97 and 39.80 MPa for control mix, mix with CFA and mix with CFBA respectively. The compressive strength of CFBA mix was 2% less than the control mix and is equivalent to the mix with CFA (Faleschini *et al.*, 2015). In these studies, the decrease in strength is attributed to the lesser availability of active silica and pozzolanic activity of the CFBA. As well as the higher water content was also found responsible for the decrease in the strength.

Water Absorption

The use of the CFBA in concrete did not cause any major change in the water absorption property of concrete. Water absorption of concrete with 0%, 5%, 15% and 25% replacement was found to be 3.50, 3.55, 3.20 and 3.33% which is comparable (Kosior-Kazberuk, 2013). Water absorption observed at the age of 7 days was 4% for control mix, 3.8% for mix with CFA and 2.1% for mix with CFBA which was least (Faleschini *et al.*, 2015). The experimental studies suggested that the inclusion of fly ashes (CFA and CFBA), resulted in a lower porosity matrix which was advantageous for decreasing the water absorption.

Resistance Against Wetting/Drying Cycles

Alternate drying and wetting cause disintegration in the concrete, which results in the decrease in strength. In concrete disintegration, salt crystallization in the conglomerate pores acts as a catalyst by causing thermal stresses (Faleschini *et al.*, 2015). Concrete specimens were subjected to 30 cycles of alternate wetting and drying and then checked for compressive strength. The observed reduction in the strength of the control mix, mix with CFA and mix with CFBA was 20%, 21%, 28% with respect to their 28 days compressive strength. The highest reduction was shown by the mix containing CFBA. Alternate wetting and drying caused the formation of micro-cracks of the width of 2–5 μm on the surface of binder matrix. The cracks were common in all the concrete specimens. The inclusion CFA and CFBA as an SCM was unable to enhance the resistance against the deterioration due to the alternate drying and wetting cycles (Faleschini *et al.*, 2015).

Freezing and Thawing

Concrete specimens containing CFBA was subjected to repeated freezing and thawing. Evaluation of surface scaling due to the freezing and thawing was quantified as per CEN/TS 12390-9:2007 (Kosior-Kazberuk, 2013). For concrete specimens (0%, 5%, 15% CFBA) with an air entraining agent (AEA) content of 0.05% of binder weight, observed scaling was below 0.6 kg/m^2 which is acceptable as per SS 13 72 44 (1995). But concrete (25% CFBA) failed to meet the same. Further, the AEA content was increased to 0.10% of binder weight and the scaling was observed in all concrete specimens after 112 cycles of freezing and thawing. Observed scaled material mass in the concrete (0%, 5%, 15% and 25% CFBA) was $0.09\text{--}0.3 \text{ kg/m}^2$, which is within the permissible limits. For a particular AEA content, an increase in the CFBA content decreased frost resistance (Kosior-Kazberuk, 2013). Mortars with cement replacement 0%, 20% by CFA, 20% by CFBA were cast. All the mortar specimens were subjected to freezing and thawing followed by compressive strength test. After 140 cycles of freezing and thawing, 40%–46% decrease in the compressive strength was observed in all the mortar samples (Johnson *et al.*, 2010). The values from these studies suggested that the inclusion of CFBA and CFA as an SCM did not cause any major alteration in freezing and thawing resistance. As well as the air content plays a major role in the freeze-thaw resistance enhancement.

Alkali-Silica Reaction (ASR) Expansion

CFBA is helpful in the reduction of the ASR expansion (Wang *et al.*, 2007). CFBA has a tendency to adsorb alkali ions and results in products which are non-expansive in nature, unlike expansive alkali-silica gel and stated that the CFBA is feasible to be used in concrete (Sarabèr and van den Berg, 2005). The same was also confirmed by the study (Wang, 2015), which focussed on the ASR expansion of the mortars containing CFBA in the proportion of 15%, 25%, 35% weight of the cement. ASR expansion observed for mortars with 15% CFBA was 0.15%–0.2%, for 25% CFBA was 0.1%–0.15% and for 35% CFBA it was found to be 0.05%–0.1%. With the increase in the CFBA percentage inclusion, ASR expansion decreased. Reduction in the ASR expansion in a mortar containing CFBA at 14 days and 28 days by 78%–94% and 68%–85% respectively lesser than standard cement mortar (Shearer, 2014).

Conclusion

The construction industry is an intensive consumer of energy and natural resources (e.g., cement, aggregates etc.). The ever increasing material demand exerts pressure on the environment, which creates a scope of opting alternate sustainable materials. CFA obtained from combustion of coal is an industrial by-product and is an important asset to the construction industry. It can be used as a binder or as an aggregate in mortar/concrete. CFBA obtained from co-combustion of coal and biomass are comparatively new and were not addressed in American Standard (ASTM C 618) and Indian Standard (IS 3812: 2003) due to its non-coal origin. Whereas, European code (EN 450-1:2009) has permitted CFBA with limitations (i.e., biomass $\leq 10\%$ of coal in the blend).

It can be stated that the biomass inclusion in the process of the direct co-firing with coal, does impact the resultant ash properties (chemical, physical and mineralogical etc.). Following conclusion is drawn from the literature:

- The inclusion of biomass (wood, wood pellets, wood chips, sawdust and switchgrass) did not cause any significant alteration in the elemental composition of the CFBA. But, it was observed in Table 4, that with the increase in the percentage inclusion of particular biomass (wood pellets and switch grass), SiO_2 content in the ash decreased.
- The alteration in the chemical properties is mainly affected by the ash content of the included biomass and its chemical composition.
- These two factors also influence the mineralogy of the CFBA. Mixed mineralogy of CFA and biomass ash was observed in the CFBA.
- Rather than the biomass kind the grain size distribution of CFBA was found to be more dependent on the combustion conditions (temperature, loading and soot blowers) and sampling position (i.e., air preheater, cyclone and filter).

Industrial waste i.e., CFBA has a potential to be used as an alternative raw material in the production of mortar/concrete. But the effect of the CFBA inclusion in the quality of the concrete needs to be assessed through conducting the required tests. Effect of CFBA inclusion, as an SCM, in concrete is

- The heat of hydration decreased when CFBA (obtained from co-combustion of wood chips and coal) was used as an SCM due to its inert behavior in the initial hydration stages.
- CFBA (resultant from co-combustion of wood chips with coal and wood pellets with coal), when used as an SCM reduced the workability. In the case of CFBA (obtained from wood chips and coal co-combustion) reduction in workability was 50%.
- Five different CFBA (with secondary fuel as PD, DW, SRF1, SRF2 and wood chips) were unable to cause significant alteration in the initial and final setting time of the cement.
- CFBA (resultant from co-combustion of wood biomass with coal and RDF with coal), due to its lesser content of reactive silica, decreased the compressive strength of concrete. However, the inclusion of these CFBA caused a decrease in the water absorption by forming the lesser porosity concrete.
- CFBA (obtained from co-combustion of coal-switchgrass, coal-sawdust and coal-pine chips) was found to be beneficial in decreasing the alkali-silica reaction by absorbing alkali-ions and resulting into the non-expansive products.
- Whereas, CFBA (obtained from co-combustion of coal-wood biomass, coal-RDF and coal-wood pellets) was found to be ineffective to enhance few properties like resistance to freezing-thawing and alternate wetting-drying.

The absence of a unique trend in the ash properties was noted. Overall, the study was helpful to assess the suitability of various CFBA as an alternate sustainable construction material and its effect on the concrete properties. The study suggests that there is a scope of consideration of such ashes in existing standard codes.

Future Scope

The aim of the review article was to highlight the feasibility of CFBA as construction material. For the evaluation of the same, various required tests associated with the raw material characterization (i.e., chemical, physical and mineralogical) were enlisted and the effect of co-combustion on these properties was discussed. The article also targets the effect of CFBA inclusion (as an SCM) on the fresh concrete and hardened concrete properties. Through the article, an attempt was made to include maximum possible properties of concrete (containing CFBA) to assess the role of CFBA in concrete quality. Still, through the literature, it is observed that there is a scope of research to evaluate the CFBA effect on the concrete properties such as splitting tensile strength, flexural strength, modulus of elasticity, bond strength, thermal conductivity and sound absorption (enlisted in [Table 3](#)). As well as, the durability of the CFBA-concrete against chemical attack (sulfate attack, physical salt attack, seawater exposure, acid attack and carbonation) needs to be addressed, prior to present CFBA as a practical solution to meet the sustainable raw material demand.

Introduction

According to the recent projections of the world population, there will be an increase in the population in the coming decades. This increase would be associated with an increase in the world energy demands. Consequently, more depletion of energy sources and more major negative impacts of non renewable energy on the global environment are expected. In terms of minimizing the effects of the projected increase in world energy demand, more investigation on the renewable energy are crucially needed to be good alternatives for non-renewable energy. Biomass is one of these renewable energy resources. It is the fourth largest primary energy resource, renewable, sustainable and a clean resource of energy that has numerous benefits, locally and globally (UN, 2015; Goswami and Kreith, 2015; Saxena *et al.*, 2007; Katuwal and Bohara, 2009). As is well known, lignocellulosic materials are available everywhere in low and stable costs. It is mainly waste materials that are containing in abundance of carbohydrates and non-competitive with food chain (Zabed *et al.*, 2016; Zhao and Xia, 2010). Biomass as an energy resource, requires conversion process to be used as a bio-fuel. AD is one of the most effective biological conversion process of biomass into bio-fuel. It breaks down organic matter by microorganism and enzymes in an oxygen-free environment to produce biogas. Generally, the final output products of AD process are biogas and digestates. Where, the biogas can be directly used in several applications or upgraded and either injected into gas grid or used as a transportation fuel in compressed natural gas (CNG) motor vehicles. While, the digestate generated usually comes in liquid and solids streams and can be further separated. It contains the remained nutrients which did not digested in the digestion process such as; ammonium and phosphates. Liquid stream has the potential to be used in agriculture as a bio-fertilizer and others while, solid stream can be composted, used for dairy bedding or applied directly to cropland. It can be also used in making of high-value bio-based products through bio-refinery concepts i.e., biodiesel (Teater *et al.*, 2011; Yue *et al.*, 2010; De Jong and Jungmeier, 2015; Van Den Hende *et al.*, 2015; Sawatdeenarunat *et al.*, 2016). The production of lignocellulosic biodiesel includes five main stages, are: feedstock pretreatment, carbohydrate scarification, aerobic fungal fermentation, lipid extraction and transesterification. Where, pretreatment is the most important steps as the all following steps in the process are highly depending on its results (Ruan *et al.*, 2013; Agustini *et al.*, 2012). Moreover, although biogas is a promising, sustainable and renewable energy substitute, the sustainable development of AD process primarily depends on the ability to deal with the excessive digestate produced. An improper handling of the digestate would contribute in serious environmental issues. Due to that and to fully utilize the digestate and convert it into useful bio-based products, the attention towards the development of new bio-refining processes, has recently increased. Several recent studies have focused on developing an integrated system including AD and fermentation process to convert various feedstocks into bio-fuel and high-value bio-based products (Wang *et al.*, 2016; Dahlin *et al.*, 2015; Zhong *et al.*, 2015). Successful application of such a system could greatly results in the double benefit of producing renewable energy while adopting a zero waste approach. However, the proposed work aims to present an overview of integration approach of AD and fermentation process to produce biogas, biodiesel and multiple bioproducts such as: livestock food, bio-fertilizer, glycerin in which they can be utilized in many applications and end up with zero waste.

Biodiesel

Biodiesel is a promising form of liquid bio-fuel. It would play a significant role in providing the energy requirements for transportation. Thus, many scientists and researchers have focused recently more on the efficiency and emissions of the biodiesel engine. According to a study on biodiesel engine performances and emissions in 2011 (Jinlin *et al.*, 2011), using of biodiesel may result in considerable drop in particulate matter PM, hydro-carbon HC and carbon monoxide CO emissions and increase in nitrogen oxides NO_x due to the higher amount of oxygen content in biodiesel comparing to conventional diesel. It may result also in reduction in engine power because of the reduction in calorific value of biodiesel compared to conventional diesel. The study has concluded that, the blends of biodiesel with low percentage of petroleum diesel can help in controlling air pollution and easing the pressure on scarce resources without influencing on engine power and economy. In comparison to bio-ethanol as a liquid bio-fuel, biodiesel stands at present in lower position than bio-ethanol because of several factors such as; lower environmental sustainability of raw materials it is obtained from, not as good as bio-ethanol in mitigation of GHG emissions, higher production cost and a less favorable future evolution (Mussatto *et al.*, 2010; Demirbas, 2007, 2011, 2009; Balat and Balat, 2009).

Conventional Diesel Versus Biodiesel

Biodiesel can be used in diesel engines. It can be also blended with petro-diesel and used in standard diesel engines in any percentage i.e.; 1% of pure biodiesel blended with 99% of petro-diesel (Extension, 2013; Sheehan *et al.*, 1998). Biodiesel has lower toxicity compared to conventional diesel. It degrades faster than diesel fuel which significantly helps in reducing the environmental consequences of bio-fuel spills. Where, the biodegradability of biodiesel highly depends on the chemical structure of the fatty acids. Biodiesel is the only alternative fuel can be used in conventional diesel engine. On the other hand, due to the low calorific value of biodiesel in comparison to normal diesel, diesel engine consumes more biodiesel than normal diesel. Biodiesel is not as stable as conventional diesel, therefore the storing of it for longer than six months is inadvisable (Romano and Sorichetti, 2011).

Anaerobic Digestion (AD)

AD is an efficient microbiological conversion process of biomass into biogas. It requires low energy and generally contributes in reducing greenhouse gases. AD has proved its significant performance in converting a wide variety of biomasses such as: edible food (1st bio-fuel generation), LCB's and wastes (2nd bio-fuel generation) and seaweeds (3rd bio-fuel generation). However, AD process breaks down the organic matter by bacteria in the absence of oxygen to produce biogas. The process is carried out in four main stages, pre-treatment, waste digestion, gas recovery or gas upgrading, and residue treatment (Al Seadi *et al.*, 2008; Dutta *et al.*, 2014).

Pretreatment stage is very important stage. The pretreatment method should be carefully selected and implemented, as the other three stages are highly relying on it. The decomposition or digestion process occurs inside the digester in four biochemical reactions. Fig. 1, below illustrates the biochemical reactions. In the hydrolysis step, organic matter is converted into basic monomers by the hydrolytic enzymes. The solubilised monomers are then fermented to organic acids and hydrogen by the fermenting bacteria (acidogens). Following that, the volatile fatty acids (VFA) are converted into acetate, carbon dioxide and hydrogen by the acetogenic bacteria. The results of the previous step are converted then by methanogens bacteria into methane and carbon dioxide. About two-thirds of the methane produced from the digestion process, originates from acetate acids. While, the remaining amount produced are derived from conversion of hydrogen and carbon dioxide. However, the final products of AD are biogas and two by-products (nutrient- rich liquid digestate and the fiber-rich solid digestate) which can be later utilized in several applications (Al Seadi *et al.*, 2008; Kelleher *et al.*, 2002; Parkin and Miller, 1983; Thomas *et al.*, 2013; Al Seadi, 2001).

Biogas

AD biogas is a promising bio-fuel, it contributes in bringing about environmental benefits globally. It is composed of different gases in different amounts. Its composition is varied depending on several factors such as feedstock types, digestion systems, temperature, retention time, etc. It is quite similar to landfill gas composition but varies from the natural gas. In comparison to natural gas, the calorific value of typical biogas (60% CH_4 and 40% CO_2) ranges from 5.5 to 6.5 kWh m^{-3} , while the calorific value of typical natural gas ranges from 5.8 to 7.8 kWh m^{-3} . Thus, biogas has the potential to be a significant alternative to natural gas and can be used in all natural gas appliances. However, biogas is able to be used in different applications, such as; heating, CHP

Fig. 1 AD Decomposition steps. Reproduced from Ersahin, M.E., Ovgun, H., Dereli, R.K., Ozturk, I., 2011. Anaerobic treatment of industrial effluents: An overview of applications. In: Einschlag, F.S.G. (Ed.), Waste Water Treatment and Reutilization. Turkey: InTech, pp. 1–28.

and fuel cell or used as chemical feedstock or may be fuel for vehicles (Monnet, 2003; Jensen, 2000; Zorn, 2005; Yu *et al.*, 2010). On the other hand, the biogas contains small traces of different impurities such as; hydrogen sulfide H_2S , ammonia NH_3 , oxygen O_2 and nitrogen N_2 . Due to that and to avoid corrosion and mechanical wear of appliance as well, biogas must be upgraded prior using it (Lamsal and Tyagi, 2010). There are a number of technologies available nowadays for scrubbing contaminants and upgrading gas to the required gas quality (e.g., Carbon dioxide removal, hydrogen sulfide removal and Siloxanes removal technology) (Monnet, 2003). The final product is practically similar to a large extent to the natural gas. It can be blended as bio-natural gas or sold separately (Browne *et al.*, 2011).

AD Digestate

The other end product of AD process is the digestate. Nitrogen, phosphorus and potassium are the three main nutrients conventional fertilizer typically contained. The content of digestate from one or more of these nutrients makes it a substitute for the conventional fertilizer. As aforementioned, digestate is produced in liquid form and can be used as it is or separated into liquid and solid digestate and use each of them separately. The amount of dry matter in both types are different. Usually, liquid digestate contains less than 15% dry matter, while the solid digestate contains more than 15%. The digestion process used and the composition of ingestates are two important factors in determining the quality of a digestate. pH level, macro-element content (such as; N, P and K), micro-element content (such as; copper Cu, zinc Zn) and organic matter content of digestate are another factors to verify the quality and stability of the digestate (Makádi *et al.*, 2012). A study in 2015 (Zhong *et al.*, 2015) claimed that, anaerobic microbes can only convert approximately 40%–60% of carbon into methane in AD of animal manure. However, utilizing the nutrients and lignocellulosic materials in the digestate is critical to significantly improve the efficiency of AD technology and produce multiple products such as: value-added chemical and fuel products from organic wastes (Teater *et al.*, 2011; Yue *et al.*, 2010; De Jong and Jungmeier, 2015; Van Den Hende *et al.*, 2015; Sawatdeenarunat *et al.*, 2016).

Production of Biodiesel

Biodiesel is produced through chemical reaction of a variety of biomass such as; oils, fats, and greases with an alcohol such as; methanol or ethanol and a catalyst like sodium hydroxide or potassium hydroxide. Soybean, rapeseed/canola, used vegetable oils, and tallow (animal fat) are the widely common biomass used in production of biodiesel. The production of biodiesel from lignocellulose biomass can be carried out through three main steps; (1) lignocellulose biomass is converted to fermentable sugar, (2) the sugars are converted to microbial lipids by oleaginous microorganism, and (3) microbial lipids are translated to biodiesel. However, the process of producing biodiesel, separates glycerin from the feedstock used (i.e., oil or fat). Thus, the final biodiesel produced is thinner than the original oil or fat and therefore performs better in a diesel engine. Furthermore, vegetable oils and animal fats used to generate biodiesel come from practically any source. Even cooking oil can be used as well for production of biodiesel. Furthermore, the chemical process applied for making biodiesel called “transesterification” (Gong *et al.*, 2013; Gerpen, 2013). On the other hand, the glycerin extracted from the process of making biodiesel has many uses. It can be used in making soap, food, ink, creams, lubrication of molds, etc. Due to the recent steady growth of using biodiesel, the production of glycerin has increased as well. Currently, there are many academic and industrial research groups for discovering new glycerin uses and applications specifically in polymers and surfactants (Claude, 1999; Gemma *et al.*, 2007).

Integration of Anaerobic Digestion and Aerobic Fungal Fermentation Process

The bio-refinery concept is quite similar to conventional petroleum refinery. It involves making full use of biomass. While, the input of the process is only the biomass, the output can be feed, food, biomaterials and bio-fuel. In other words, the bio-refinery concept is a facility that integrates biomass conversion processes and equipments to produce feed, food, biomaterials, bio-fuel, etc (Sawatdeenarunat *et al.*, 2016). Fig. 2, illustrates a simplified scheme of bio-refinery concept.

Moreover, a study in 2014 (Zhong *et al.*, 2015) was carried out to produce lignocellulosic biogas and biodiesel through an integration approach of AD and aerobic fungal fermentation. Generally, the study has concerned on developing an integrated system including AD and aerobic fungal fermentation in order to convert corn stover, animal manure and food wastes into microbial lipids for production of biodiesel. Fig. 3, below illustrates the integration process of producing biogas and biodiesel. In the production of biogas, the main feedstock was animal manure and a small amount of food wastes which was used to balance nutrient to enhance AD performance. While, in the production of biodiesel, AD fiber was used as the main feedstock for fermentation stage. Corn stover as an agro-industrial waste was used as a solid support, carbon source and nutrient source in the solid state fermentation process. Large amount of agro-industrial wastes are basically composed of cellulose, hemicelluloses and lignin and being called lignocellulose biomass (Zabed *et al.*, 2016). Stalk, leaves, husk, shell, peel, etc. are some types of agro-Industrial wastes. They are mainly contain of water and rich in sugar, minerals and protein which have made them suitable environment for the development of microorganisms, basically fungal strains, which are able to rapidly grow in these wastes. Due to that, they should not be considered as “waste” but lignocellulose raw material for other industrial processes (Mussatto *et al.*, 2012). In the study (Zhong *et al.*, 2015), the combined

Fig. 2 Simplified scheme of bio-refinery concept. Adapted from Koltuniewicz, A.B., 2014. Bioprocesses. In: Sustainable Process Engineering: Prospects and Opportunities. Berlin: Walter DeGruyter, pp. 269–346.

Fig. 3 Flowchart of the integration process. Reproduced from Zhong, Y., Ruan, Z., Zhong, Y., *et al.*, 2015. A self-sustaining advanced lignocellulosic biofuel production by integration of anaerobic digestion and aerobic fungal fermentation. *Bioresource Technology* 179, 173–179.

hydrolysis of corn stover and AD fiber were accomplished by enzymatic hydrolysis of the combined slurry. **Fig. 4**, also shows the mass flow of the integrated system. This integrated process has ended up with producing of 1 L of biodiesel and 1.9 kg CH_4 from (12.8 kg dry dairy manure, 3.1 kg dry food wastes and 12.2 kg dry corn stover) with a positive net energy of 57 MJ. The study has concluded that, combined hydrolysis of alkali treated AD fiber and acid treated corn stover is technically feasible for converting agricultural residues into mono-sugars without neutralization and detoxification.

Moreover, the biodiesel production process begun by separating AD effluent into two streams: nitrogen and phosphorus-rich liquid digestate and fiber-rich solid digestate. Commercial screw press separator with 2 mm screen was used to do so. After that, dilute alkali pretreatment was applied to treat the AD fiber at specific condition (temperature, °C, time, h and NaOH, %). While, corn stover was pretreated at certain condition as well (temperature, °C, time, h and sulfuric acid concentration, %) by dilute acid pretreatment. Total solid concentration of the two pretreated slurries were then adjusted and thoroughly mixed at a ratio of 1:1 (wt/wt) to form combined slurry. For carrying out the enzymatic hydrolysis at certain condition (temperature, °C, rotate speed, rpm), an enzyme mixture was applied on the combined slurry in a shaking incubator. In order to separate the liquid hydrolysate from the residual solids, the hydrolysate was centrifuged. For sugar analysis, about 5 ml of the liquid hydrolysate was taken and filtered through a 0.22 μ m polyether-sulfone membrane filter. The remaining liquid hydrolysate was being used then for fungal lipid fermentation. Beyond that, the right oleaginous microorganism should be carefully selected to be used in accumulation of lipid on the hydrolysate. Where, microorganism which include bacteria, fungi, yeast, mold and microalgae that can accumulate lipids up to 20% or more of their dry weight are considered as oleaginous microorganism (Liang and Jiang, 2013). Fungal lipid accumulation was then fulfilled in Erlenmeyer flask with an amount of medium. Before being sterilized at specific temperature and time, a certain percentage of NaOH was applied to the fermentation medium to adjust the pH level. The fermentation medium was inoculated with a (vol/vol)% seed and cultivated for particular days at certain temperature on a rotary shaker with an agitation speed (rpm). Fungal biomass was collected by filtration and washed twice with distilled water over a Whatman #1 filter paper. In order to obtain a consistent weight, cell mass was determined by drying at certain temperature. Dried mycelia were ground in a mortar and used for lipid extraction. Total lipid was lastly determined gravimetrically (Zhong *et al.*, 2015).

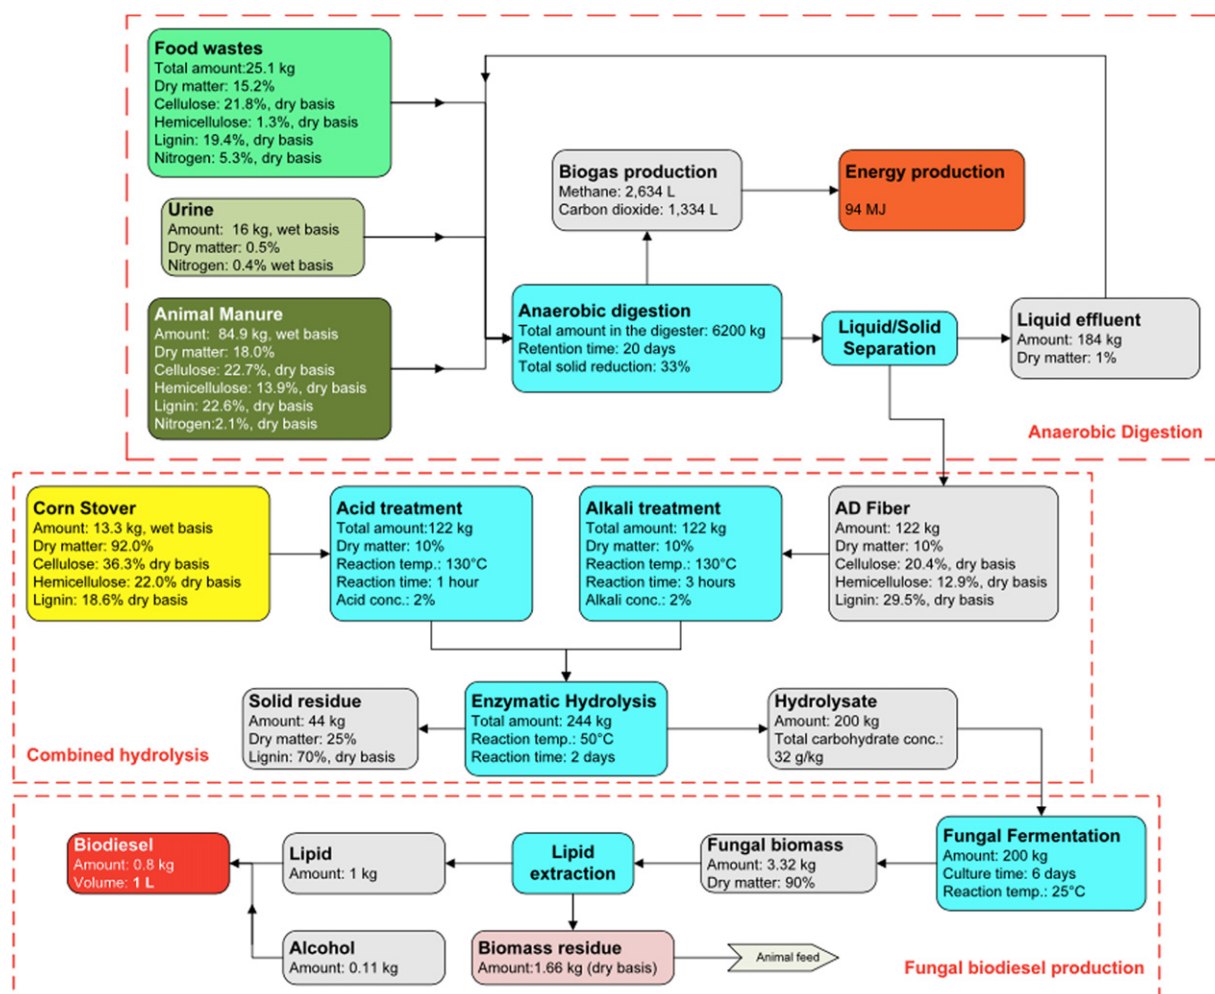

Fig. 4 Mass flow of the integrated process. Reproduced from Zhong, Y., Ruan, Z., Zhong, Y., *et al.*, 2015. A self-sustaining advanced lignocellulosic biofuel production by integration of anaerobic digestion and aerobic fungal fermentation. *Bioresource Technology* 179, 173–179.

However, several previous studies (Teater *et al.*, 2011; Zhong *et al.*, 2015) have confirmed that AD fiber has the potential to provide the same performance as a feedstock for both bio-ethanol and biodiesel productions. Of course, that would greatly contribute in expanding the potential application of AD solid digestate and improving the economical benefits of AD process (Teater *et al.*, 2011; Zhong *et al.*, 2015; Mohan *et al.*, 2010). Zhong *et al.* (2016) have revealed that, although AD consumes a high proportions of organic matter in the waste, AD digestate still contains a significant amount of nutrients as well as lignocellulosic substances. This study (Zhong *et al.*, 2016) has mainly aimed to develop an integrated system that the biogas produced is later used to power fungal fermentation and convert the existed carbon source, nutrients and water in the digestate into bio-fuel precursor-lipid. This would help in developing a fresh-water-free and energy-positive process to simultaneously utilize both solid and liquid digestate in the accumulation of fungal lipid for biodiesel production. The integrated system contains two unit operation, which are, AD and digestate utilization. Digestate utilization includes five main stages, are; digestate pretreatment, enzymatic hydrolysis for mono-sugar release, over-liming detoxification and lastly fungal fermentation for lipid accumulation. In order to release mono-sugar, the mixture of solid and liquid digestate was pretreated at certain conditions and hydrolyzed, by alkali and enzyme respectively. In the pretreatment process, liquid digestate was used as the processing water. After releasing of mono-sugar, over liming detoxification was applied to prepare the hydrolysate for fungal fermentation. The results have indicated that, the studied integrated system has the potential to offer optimal solutions for bio-fuel production and waste management and the fresh-water-free and energy-positive process was significantly developed to utilize solid and liquid digestate to the accumulate fungal lipid and subsequently produce biodiesel.

The Importance of the Pretreatment of Biomass

Pretreatment methods are mainly classified into the following group: physical (mechanical) such as; milling, beating, ultrasonic and collision plate pretreatment, chemical (e.g., alkaline and acid pretreatment), and biological (e.g., fungal pretreatment).

Table 1 Biogas yield from different mechanical pretreatment methods of feedstock

Physical pretreatment	Feedstock	Pretreatment conditions	Results
Comminution	● Agricultural residuals: wheat straw, rice straw, oat, clover, bagasse, coconut fiber, hemp, banana peelings, cauliflower leaves, and digested bio-fibers. ● Forest residuals: mirabilis leaves ● Grass: dump grass and grass hay ● Municipal solid waste (MSW): organic fraction of MSW (OFMSW)	Particle size: 0.003–30 mm	Up to 30% improvement of methane yield. Occasionally, reduced size decreased biogas production
Steam-explosion	● Agricultural residuals: wheat straw, corn stalks, corn straw, citrus waste, potato pulp, rape straw, and digested bio-fibers ● Hardwood: Japanese cedar, willow, and birch ● Grass: bulrush, Miscanthus, and seaweed ● MSW: OFMSW and paper tube residuals ● Softwood: bamboo	160–260°C, 0.7–4.8 MPa, and seconds to a few minutes	Positive effect of up to 40% increase in biogas yield. Occasional zero or negative effect also occurred
Liquid hot water (LHW)	● Agricultural residuals: Wheat straw, rice straw, oil palm empty fruit bunches (OPEFB), sunflower stalks, and sugarcane bagasse ● Grass: Miscanthus and hybrid grass ● MSW: OFMSW and paper tube residuals	100–230°C (0.1–2.8 MPa) for a few minutes to hours	7%–220% increase of methane yield
Extrusion	● Agricultural residuals: barley straw, maize, and solid fraction of manure ● Grass: Lolium multiflorum and pelleted hay ● MSW: OFMSW	0.45–3.5 MPa for a few minutes (e.g., 4–12 min) and typical temperature of 60–90°C	8%–70% improvement of methane yield
Irradiation	● Agricultural residuals: wheat straw, barley straw, spring wheat, winter wheat, oat straw, and rice stalks ● Grass: switchgrass and hybrid grass MSW: OFMSW	115–300°C for a few minutes to hours	4%–28% improvement of methane yield. No or adverse effects were found. Combination with acids or alkali could achieve greater improvement of biogas yield

Note: Zheng, Y., Zhao, J., Xu, F., Li, Y., 2014. Review: Pretreatment of lignocellulosic biomass for enhanced biogas. *Progress in Energy and Combustion Science*, 35–53.

Various types of pretreatment methods have been extensively investigated on the pretreatment of different types of biomass. The effectiveness of the different pretreatment methods on the biomass from even the same pretreatment group is varied from each others. For instance, a study in 2015 (Montingelli, 2015) has compared between three different mechanical pretreatment methods, are; microwave, milling and beating methods on different species of Irish seaweeds. The study has concluded that, the greatest performance in terms of methane production was achieved when a beating pretreatment was applied. Whilst, the other two methods have negatively affected the digestion process, beating pretreatment is relatively a new mechanical pretreatment method was first introduced by the biomass research team in Dublin City University in 2011 based on employing Hollander beater device. This method has proved its performance in pretreatment of only few biomasses such as; seaweed, maize silage, fresh grass and potato wastes, but it is not yet widely applied. Table 1, presents the biogas yields which has been resulted after several mechanical pretreatment methods on different types of biomasses.

However, as the pretreatment is the most important step in the biomass conversion process as it has a major influence on all the other steps in the process. The optimum goal of the pretreatment process is to enhance the enzymatic hydrolysis of carbohydrates (cellulose and hemi-cellulose) therefore increasing the overall bioconversion efficiency for production of sugars. According to some previous studies, Alkaline pretreatment is one of the most viable process options, mainly due to its significant pretreatment effect and relatively simple process scheme. Alkaline pretreatment has a principal feature that, it selectively takes off lignin without degrading carbohydrates, and increases porosity and surface area, thereby improving enzymatic hydrolysis. Table 2, illustrates the difference in effect between several pretreatment methods through showing the extent of the effects of some different pretreatment methods on the compositional and structural alteration of lignocellulosic materials.

Furthermore, as an integrated approach of AD and fermentation process, pretreatment plays a crucial role because the design of the subsequent scarification and fermentation processes highly depending on the result of the pretreatment step. Thus, the following criteria should be considered for selecting the most effective and appropriate pretreatment methods: should require low capital and operational costs, require minimum size reduction of the biomass, toxic compounds produced under the pretreatment conditions should be minimum, etc. However, a pretreatment method should be carefully selected and implemented prior to the combined hydrolysis of agro-industrial wastes and AD fiber which is carried out by enzymatic hydrolysis of the combined slurry (Agustini *et al.*, 2012; Mosier *et al.*, 2005; Alvira *et al.*, 2010; Yang and Wyman, 2008).

Table 2 Illustrates the difference in effect between several pretreatment methods

Pretreatment	Increase of accessible surface area	Decrystallization of cellulose	Solubilization of hemi-cellulose	Solubilization of lignin	Alteration of lignin structure	Formation of furfural/hydroxymethylfurfural (HMF)

Discussion

As previously mentioned, there will be a number of issues associated with AD when it is applied extensively. These issues have made the investment in AD less attractive or maybe not economically feasible. These issues are categorized into three categories: operational, economical and environmental issues. Generally, there are number of operational factors that must be considered in advance to be avoided. These factors can result in a failure or the poor operational stability of the system such as: inadequate operational management, lack of process control, external disturbances, and others. In addition, personnel qualifications is considered another operational factor should be taken into account to professionally monitor and control the system. Economically, as the biogas is the single main product of AD, the production of AD biogas can be not economically competitive with its counterparts due to: (1) the amount of energy consumed in AD process especially, the energy consumed in the pretreatment and digestion and, (2) the fluctuation of fossil fuel price indexes. The production of more bio-products could be a significant solution for increasing the economical viability of AD. While, the environmental issues lie in the accumulation and the improper handling of the huge the digestate which can lead to serious environmental issues. Practically, there are some ways to overcome the environmental issues, one of these ways is to utilize the digestate in other applications. As mentioned before, anaerobic microbes can convert only from 40% to 60% of carbon into methane. AD digestate contains significant quantity of nutrients and lignocellulose materials which has not been digested in the digestion process. Thus, making a use of the digestate to produce bio-fuel or bio-products would greatly contribute in overcoming the AD economical and environmental issues.

On the other hand, as the digestate still contain undigested materials, it is required to be pretreated. Pretreatment step is the most important step as the other following steps in the biomass conversion processes are relying on its results. Thus, pretreatment method must be selected based on the aforementioned criteria in Section “The Importance of the Pretreatment of Biomass”.

However, the integration approach corresponds to the refinery concept. It is incorporating bioconversion processes to produce multiple bio-products. Many integration approaches of the biomass conversion processes have confirmed their potentials in some previous scientific studies. This approach could help in making a full use of byproducts and biomass, increasing the economical profit, minimizing the wastes, producing bio-fuel and high-value bio-based products simultaneously and improve the industrial values of the production of bio-fuels. Regarding to the production of biodiesel, various studies have proved the capability of the residual biomass to be used as animal feed or feedstock for AD to produce biogas. The glycerin extracted from biodiesel production process can be considered as by products and used further in different applications i.e., soap making. The digestate can be used as bio-fertilizer or soil amendment in agricultural applications. However, much attention have been paid recently towards the development of integrated approaches as it can be a significant and radical solution for AD issues. But, more studies are still required to exploit more biomass other than the conventional ones in order to discover and produce more by products and bio-products. The successful application of the integration approach on the non-conventional biomass would certainly contribute in making AD prosper and the investment in it is much more attractive. A substantial positive changes will be clearly noted when this system proves its effectiveness and capability to prosper.

Conclusion

Biodiesel is a promising form of liquid bio-fuel. Integration approach of producing bio-fuel, bio-products and high-value bio-based products from AD fiber is a new approach. Investigation of the effectiveness of more pretreatment methods on AD fiber prior to the enzymatic hydrolysis is strongly needed for further studies. That can be accomplished by comparing the pretreatment methods which have been applied in previous studies with other methods. However, scientific literatures on the production of lignocellulosic biodiesel through integration system are relatively low. An integration approach has the potential to offer optimal solutions for bio-fuel production and waste management. But, to end up with better integration system, more investigations regarding to several aspects such as; feedstocks used, pretreatment technique, economic analysis, agro-industrial waste applied and others are highly required.

Acknowledgments

The authors would like to gratefully acknowledge Saudi Cultural Bureau for funded this study. Great thanks also express to Dublin City University, Dublin, Ireland for providing the appropriate environment for researchers to do their works and enable them to easy access to the enormous amount of research and scientific publications worldwide.

Plastic Recycling

The extreme use of plastic product in the present scenario leads to intense interest in the recycling and reuse of end products (Francis, 2016). Worldwide, the production of plastics was 168 million tons in the year 1999 and approximately 210 million tons in 2010. Since the treatment of plastic wastes has become a serious problem, the development of effective recycling processes is urgently needed (Goto, 2009). The waste management hierarchy indicates an order of preference for action to reduce and manage plastic waste, and is usually presented diagrammatically in the form of a pyramid (Fig. 1). The recycling of plastics products are fit into the waste hierarchy as an efficient and sustainable use of material resources. As per waste management hierarchy, plastic waste can be minimized at the different level following prevention to disposal. The prevention is most preferred, whereas disposal is least (Gertsakis and Lewis, 2003). The society should prefer logically the prevention rather than level of recycling to minimize the chances of pollution spread because it should be noted that reuse, recycle and recovery phase are the energy and resource consuming processes whereas disposal can lead serious hazards. Based upon the waste management concept, plastic recycling can be broadly divided in the four classifications namely: primary, secondary, tertiary and quaternary recycling. Primary and secondary recycling (recycling of clean, uncontaminated and single type waste: extrusion, molding, heat treatment) are actually the mechanical recycling, tertiary recycling are performed by chemical mean (dividing plastic waste into smaller molecules) and quaternary recycling is disposal by thermal utilization specially by energy recovery.

The primary recycling is an uncontaminated process in which only molecular arrangement/behavior are modified to applied the material in different processes (Singh *et al.*, 2017a). Reduction of average molecular weight, increase of average molecular weight, formation of cyclization/unsaturation, remedial combination of molecules, dehydrohalogenation are some of the techniques which termed as the primary recycling process (Kaminsky *et al.*, 1976; See Fig. 2).

The secondary recycling is a mechanical mean of recycling process where polymers like, Polyvinyl styrene (PVS), low density polyethylene (LDPE), high density polyethylene (HDPE), acrylonitrile butadiene styrene (ABS), Polypropylene (PP), Polyethylene terephthalate (PET), Polystyrene (PS), Polycarbonate (PC), polyamides (PA) and etc. are largely modified for preparation of feedstock or useful products (Seike *et al.*, 2018; Soo *et al.*, 2017; Wan *et al.*, 2017; Singh *et al.*, 2017b,c,d,f,e). As reported by the various studies, extrusion is the most effective tool of secondary recycling in which the material are modified as used for the preparation of feedstock (Kumar *et al.*, 2017a,b,c,d, 2018). The metallic/nonmetallic/alloys particle are directly incorporated in the material matrix to modify melt flow behavior, molecular density, tensile properties, hardness, surface, thermal and chemical properties (Maris *et al.*, 2017; Ragaert *et al.*, 2017; Singh *et al.*, 2016a,b). Additive manufacturing/3D printing is also termed under the secondary recycling where useful products are fabricated with provision of recycling. The tertiary recycling process involves various methods of recycling including cracking, gasification, thermolysis and chemolysis (Hahladakis *et al.*, 2017; Horvat and Ng, 1999; López *et al.*, 2013). As the process of polymerization combines the monomer for

Fig. 1 Waste management hierarchy. Reproduced from Papargyropoulou, E., Lozano, R., Steinberger, J.K., Wright, N., bin Ujang, Z., 2014. The food waste hierarchy as a framework for the management of food surplus and food waste. *Journal of Cleaner Production* 76, 106–115.

Fig. 2 Recycling techniques for thermoplastic materials.

production of polymer by polymerization, similarly depolymerization is termed under the tertiary recycling process where monomer are formed by breaking chains of polymers. Fourth stage of recycling is also called 'energy recovery', the useful retrieval of the energy content of plastic wastes by its use as an energy source to produce products such as steam and/or electricity. 'Incineration' is the quaternary recycling techniques which is performed under the controlled combustion of the waste polymer. A small amount of the residue is the byproduct of this process which is further landfill or treated for environmental exposure (Gurgul *et al.*, 2018; Hwang *et al.*, 2017; Roes *et al.*, 2012; Taylor *et al.*, 2014). Table 1 shows the categories and their properties of thermoplastics generally used by society.

Case Studies for Recycling of Plastic Product to Minimize Environmental Pollution

The natural fibers are bio-compatible/bio-degradable/renewable/non-abrasive in nature and possess high mechanical and heat capacity values. In this article, sustainable waste management is focused on the development of thermoplastic composite materials reinforced with natural banana fibers (BF). BF is one of the cost effective agricultural waste materials (available in abundance) having high bio-degradability and biocompatibility. Three case studies are being reported in the present article to investigate the effects of BF reinforcement in ABS, PA6, HDPE and LDPE matrix on mechanical, thermal and morphological properties.

Effects of BF on Primary Recycled ABS and PA6 (Case Study: 1)

For enhancing the mechanical, thermal and morphological properties in terms of sustainability, primary recycled ABS and PA6 a case study has been taken which was conducted by Singh *et al.* (2018). The BF (size: length 1000 μm and diameter 100 μm ; Shape: cylindrical) were prepared at lab scale by following procedure (See Fig. 3):

A combination of 5% BF has been selected to reinforce with both of the polymer matrix; ABS and PA6 independently. Finally 4 compositions/proportions have been selected for experimentation; (i) recycled ABS, (ii) recycled ABS-5% BF (by weight), (iii) recycled PA6, (iv) recycled PA6-5% BF (by weight).

The recycling of BF reinforced ABS and PA6 have been performed by TSE for producing feedstock filaments for fused deposition modeling (FDM). The pilot experimentation was conducted and input process parameter was decided based upon the uniformity of the filament extruded. Except temperature, nozzle diameter and operating torque were the two other input parameters which have significant effect on the change in the properties of the obtained feedstock filaments. The temperature for extrusion has been selected based upon differential scanning calorimetry (DSC) results obtained (225.01 $^{\circ}\text{C}$ for PA6-5%BF), for better mixing of the BF with PA6 matrix, the extrusion temperature should be greater than the melting point so the temperature of 230 $^{\circ}\text{C}$ has been selected. The acceptable diameter for feedstock filaments to be compatible with FDM is 1.75 mm, so the nozzle diameter has been selected as 1.5 mm. During pilot experimentation it was experienced that the feedstock filaments of PA6-5%BF were obtained

Table 1 Thermoplastics and their properties (www.PolymerProcessing.com, www.engineeringtoolbox.com, www.dynalabcorp.com, www.sigmaldrich.com, www.polymerprocessing.com)

Plastic	Melting point (°C)	Glass transition temperature (°C)	Young's modulus (GPa)	Applications
PC	225	145	2.6	Beverage bottles; baby milk bottles. Non-packaging uses for PC: compact discs; "unbreakable" glazing; electronic apparatus housings; lenses including sunglasses, prescription glasses, automotive headlamps, riot shields, instrument panels
HDPE	130	– 125	0.8	Water pipes, hula hoop rings, five gallon buckets, milk, juice and water bottles; grocery bags, some shampoo/toiletry bottles
LDPE	120	– 125	0.17–0.28	Frozen food bags; squeezable bottles, e.g., honey, mustard; cling films; flexible container lids
PET	250	76	2–2.7	Soft drink, water and salad dressing bottles; peanut butter and jam jars; small consumer electronics
PP	173	– 10	1.5–2	Reusable microwaveable ware; kitchenware; yogurt containers; margarine tubs; microwaveable disposable take-away containers; disposable cups; soft drink bottle caps; plates
PVC	240	85	2.4–4.1	Blister packaging for non-food items; cling films for non-food use. May be used for food packaging with the addition of the plasticizers needed to make natively rigid PVC flexible.
PS	240	100	3–3.5	Nonpackaging uses are electrical cable insulation; rigid piping; vinyl records Egg cartons; packing peanuts; disposable cups, plates, trays and cutlery; disposable take-away containers

**Fig. 3** Steps in BF processing.**Table 2** Processing condition to BF reinforced ABS and PA6

Temperature (°C)	Nozzle diameter (mm)	Torque (N m)
230	1.5	0.10

uniformly at torque of 0.10 N.m, so the levels of all the three parameter have been selected in given range. **Table 2** shows the processing variables for BF reinforced ABS and PA6.

After preparations of the feedstock filament it was fed to the commercial FDM setup to fabricate the parts to check the printing capabilities of the banana reinforced polymers for different engineering applications. The tensile part was fabricated with nozzle diameter of 0.3 mm, filament diameter of 1.75 mm. The other fixed input parameters of FDM were: layer height 0.4 mm, number of perimeter 3 (by adjusting 3 top and 3 bottom layers), fill density 100%, honeycomb fill pattern, perimeter speed 30 mm/sec,

infill speed of 60 mm/sec, travel speed of 130 mm/sec, at extrusion temperature of 250°C and bed temperature of 55°C. All these input parameters are controllable through commercial open source FDM software.

Effects of BF on thermal properties of ABS and PA6

The DSC analysis has been used to check the changes in the thermal behavior of the banana reinforced polymer contributing to the waste management for sustainable development. The DSC was conducted in between temperature range of 30–250°C under heating rate of 10°C/min controlling N₂ gas supply of 50 ml/min in two repeated cycles. Initially sample of recycled ABS (without reinforcement of BF) has been selected for DSC analysis followed by ABS reinforced with 5% BF (ABS-5BF). It is observed that melting point of virgin ABS was 190.12°C and one of the reinforcement can lead to the more thermal stability in the ABS polymer. after 5%BF to their matrix it was shifted to high as 210.35°C. This result shows that reinforcement of BF to ABS results in better thermal stability. Similar melting point of PA6 was shifted from 216.69 to 225.01°C after 5% Bf shows the enhancement of thermal stability. [Table 3](#) shows melting points of different samples.

Effects on BF on mechanical properties of ABS and PA6

To check the durability of the BF reinforced feedstock filaments prepared by the extrusion process, sample feed stock filaments were tested on universal tensile tester in accordance with ASTM D638. The load characteristics (peak load and break load), elongation characteristics (peak elongation, break elongation, percentage peak elongation, percentage elongation at break), tensile strength (peak strength and break strength), and modulus of elasticity (Young's modulus) were calculated/measured to ensure the relative durability comparison of reinforced and un-reinforced feedstock filaments of FDM. The reinforcement of the BF led to the increase in the break load and peak load in the both polymer matrix. It was observed that in case of ABS peak strength was increase from 3.791 to 4.208 kgf after 5% reinforcement where as in PA6 it was increased from 7.016 to 9.65 respectively. Similarly significant rise in the break strength was observed in the case of break strength. Similarly it was observed that in case of ABS the peak and break elongation was reduced after reinforcement of BFs whereas in case of PA6 a significant increase of elongation was observed. As observed in the case of ABS, percentage peak elongation and break elongation was reduced from 4.38% to 3.8%. In case of PA6 it was observed that an excellent rise in the elongation occurred, peak elongation was increased from 10.52% to 20.17% whereas break elongation was increased from 11.4% to 58.17% after 5% reinforcement of BF. After 5% reinforcement of BF, the Young's modulus of the ABS was reduced from 55.29 MPa to 23.1 MPa whereas Young's modulus of PA6 was increased from 35.39 MPa to 126.98 MPa (See [Table 4](#)).

Effects on BF on porosities of ABS and PA6

The micrographic observations have been made with the help of metallurgical image analysis software (MIAS). Porosities on the surface have been checked to understand the reasons for changes in the mechanical strength of the feedstock filaments. All the surfaces of extruded filament have been checked at 200X as per ASTM B 276. Extruded, non-reinforced and recycled ABS and PA6 filaments are having more voids and pores. After the reinforcement of BF at 5% by weight it was observed that a refined surface was obtained in both of the polymer matrix (See [Table 5](#)). Usually extrusion processes are resulted in the creation of voids and pores at the internal as well as external molecular arrangements. The micro-holes presented at the surfaces increases the porosity at the surface. In the present case the impact of the BF has been noted as it perfectly fill the voids and hole during the extrusion process. So the reinforcement of the banana fibers is associated with the enhancement of the porosity at the surfaces.

Table 5 Percentage changes in porosities on surface

Property	Virgin ABS	ABS with 5%BF	Virgin PA6	PA6 with 5%BF
Porosity (%)	48.79	11.3	46.95	24.18

Table 6 Control log of experiment and mechanical properties

Experiment no.	Temperature	Screw speed (RPM)	HDPE:BF	Peak load (N)	Peak strength (N/mm ²)
1	120	20	99:1	24.98	9.82

9	140	30	98:2	31.43	12.39
Unreinforced recycled HDPE				24.20	5.65

Effects of BF on Secondary Recycled HDPE (Case Study: 2)

For enhancing the mechanical, thermal properties in terms of sustainability, secondary recycled HDPE a case study has been taken which was conducted by (Singh *et al.*, 2017b). The BF (size: length 1000 μm and diameter 100 μm ; Shape: cylindrical) were prepared at lab scale by following procedure given in Fig. 3. There are three material (1%, 2% and 3% BF to HDPE), temperature (120, 130 and 140°C) and RPM (20, 25 and 30) combinations have been taken to perform the TSE. A control log based upon the Taguchi L9 orthogonal array has been developed to perform the TSE operation. Thermal (melting point) and mechanical properties (Peak load and peak strength) have been investigated on the experimental run.

Effect of BF on melting points of secondary recycled HDPE

DSC analysis of unreinforced and BF reinforced have been conducted to check the melting points of secondary recycled HDPE. It was observed that unreinforced HDPE resulted in melting point of 121.74°C. Whereas melting point of BF reinforced HDPE observed as 123°C. A little change in the melting point of the samples shows the tendency of the HDPE as the thermally stable material.

Effect of BF on mechanical properties of secondary recycled HDPE

There are three parameter has been taken i.e., temperature, RPM and proportion of matrix material and reinforcement. Feedstock filaments for FDM based on this Taguchi L9 has been prepared and tested on UTM for their mechanical strength. Control log of experiment has been shown in Table 6. Further analysis of this design has been done by Minitab software and results have been obtained for SN ratio and mean values. Analysis for peak strength, peak load has been done. Graphs for the same have also been obtained and shown in Fig. 4. From Fig. 4, it has been observed that increase in temperature resulted into SN ratio up to a certain limit but then after increase in temperature resulted into increase in SN ratio. Further in case of RPM increase in value resulted into increase in SN ratio. Hence it can be concluded that higher temperature and RPM gives the better results. It has been observed that as the temperature increases value of peak load increases. Same trend has been observed in case of RPM. However in case of proportions different trend was obtained as value of peak load decreases.

Here it should be noted that 140°C temperature, 30 RPM and 99:1 HDPE:BF ratio have been mostly contributing for changes in peak load and peak strength. (See Fig. 4).

It was observed that for peak load temperature contributed 64.23%, RPM 34.29% and HDPE:BF ratio 1.37%. Similarly for Peak strength temperature contributed 63.18%, RPM 35.38 and HDPE:BF 1.03% (See Table 7).

Effects of BF on Secondary Recycled LDPE (Case Study: 3)

For enhancing the mechanical, thermal properties in terms of sustainability, secondary recycled LDPE a case study has been taken which was conducted by (Bedi *et al.*, 2017). The BF (size: length 1000 μm and diameter 100 μm ; Shape: cylindrical) were prepared at lab scale by following procedure given in Fig. 3. There are three material combination (1%, 2% and 3% BF to LDPE), temperature (110, 120 and 130°C) and RPM (20, 25 and 30) combinations have been taken to perform the TSE. A control log

Fig. 4 Linear model for SN ratio of Peak load and peak strength.

Table 7 Percentage contribution of input process parameter

Properties	Temperature	Screw speed (RPM)	HDPE:BF ratio
Peak load	64.23%	34.29%	1.37%
Peak strength	63.18%	35.38%	1.03%

based upon the Taguchi L9 orthogonal array has been developed to perform the TSE operation. Thermal (melting point) and mechanical properties (Peak load and peak strength) have been investigated on the experimental run.

Effect of BF on melting points of secondary recycled LDPE

It clearly depicts the number of cycles of testing on DSC machine. Repetitions were necessary to eliminate any sort of effect arisen due to contamination and pre stored history. First cycle has probably removed the above said effect. Further melting range of the material can be clearly seen in graph in hatched area i.e., 126–129°C. Melting of material starts at 126°C and goes to 129°C. Enthalpy in that melting range was counted to be – 94.34 mJ with a trend. In first cycle of the DSC testing a heaped hatched curve was seen after the melting of LDPE. This shows the decomposition of some substance but surely this is not LDPE, as LDPE decomposes above 300°C. So, this might be decomposition of some of contamination present in the form of the pigment (color). After that, cooling cycle starts and sudden cooling can be seen as straight vertical line. It can be easily observed that there is no evidence of decomposition of LDPE. Some uniformity has been observed in 2nd and 3rd cycle also without any evidence of LDPE decomposition. After 3 cycles of heating, no significant effect was observed in terms of melting and decomposition of material thus it can be concluded that the part prepared from such filament wire will have higher life cycle. It has been observed that melting of the material has occurred at 121.35°C. In case of recycled LDPE, melting temperature was almost same as in case of reinforced LDPE i.e., 123°C.

Effect of BF on mechanical properties of secondary recycled LDPE

There are three parameter has been taken i.e., temperature, RPM and proportion of matrix material and reinforcement. Feedstock filaments for FDM based on this Taguchi L9 has been prepared and tested on UTM for their mechanical strength. Control log of experiment has been shown in Table 8. Further analysis of this design has been done by Minitab software and results have been obtained for SN ratio and mean values. Analysis for peak strength, peak load has been done. Graphs for the same have also been obtained and shown in Fig. 5.

Here it should be noted that 110°C temperature, 30 RPM and 98:2 LDPE:BF ratio have been mostly contributed for changes in peak load and peak strength. (See Fig. 5).

It was observed that for peak load temperature contributed 54.65%, RPM 36.68% and LDPE: BF ratio 7.08%. Similarly for Peak strength temperature contributed 54.95%, RPM 36.35% and LDPE: BF 7.20% (See Table 9).

Summary

The article presents collective case studies for prospect of recycling of plastic product to minimize environmental pollution. The case studies have been reported in the present article to see the effect of BF reinforcement in the primary recycled polymers (ABS,

PA6) and secondary recycled polymers (HDPE, LDPE). The following observations have been made from the present study of recycling by mean of extrusion process:

- The BF reinforcement has contributed for improving load resistive capacity of ABS polymer matrix, whereas it has adversely contributed for elongation and Young's modulus. After reinforcement of 5% BF, peak load was increased by 16.27% and peak strength by 10.99%. The elongation was decreased by 13.24%, Young's modulus by 52.22%.
- In the case of recycled PA6 polymer, with the reinforcement MOF 5% BF all mechanical properties have been improved. Peak load was increased by 29.07%, peak strength by 37.52%, elongation at peak by 91.73% and Young's modulus by 258.8%.
- In case of secondary recycled HDPE, it was observed that for peak load temperature contributed 64.23%, RPM 34.29% and HDPE:BF ratio 1.37%. Similarly for Peak strength temperature contributed 63.18%, RPM 35.38 and HDPE:BF 1.03%. Also it was noted that 140°C temperature, 30 RPM and 99:1 HDPE:BF ratio have been mostly contributed for changes in peak load and peak strength.
- In case of secondary recycled LDPE, it was observed that for peak load temperature contributed 54.65%, RPM 36.68% and LDPE: BF ratio 7.08%. Similarly for Peak strength temperature contributed 54.95%, RPM 36.35% and LDPE: BF 7.20%. Also it was noted that 110°C temperature, 30 RPM and 98:2 LDPE:BF ratio have been mostly contributed for changes in peak load and peak strength.

Finally it may be concluded that by reinforcement of BF into various thermoplastics, tailor made mechanical/thermal properties can be attained. Hence for ensuring the recycling of thermoplastics the reinforcement with natural fibers may be one of the cost effective solutions.

Introduction

Innovative technology has created a new path of technological application in mainstream market with the promise of environmental sustainability. In order to caution the technology players about this new trend, Malaysian government has announced that 2017 is the starting point of Industrial Revolution 4.0 (IR4.0). IR4.0 can be described as the automation and digitization of industrial processes through robotics and emerging technologies. It includes cyber-physical systems, the internet of things, cloud computing and cognitive computing. It has the ability to disrupt any current industrial processes and moves towards the creation of smart factory. Concurrently, geospatial technology, which is the process of data collection associated with geographic or locational component has gaining huge popularity due to its ability to embrace the emerging technology as described in IR4.0. This technology has rapidly rising in Malaysia since 2010.

Geospatial technology has become an important area to be studied because it involves the aspect of geological analyses, real estate and city planning and educating people (Groger and Plumer, 2012). It means, this technology has become a crucial element in any modern-day system development (Thymianidis, 2015). Most importantly, it helps emergency response and military planning, in which geospatial will generate documentations of location, contour, mapping, environmental condition and many more. All these components cannot be tracked by humans in real time simultaneously due to the lack of transport and communication systems. In Malaysia, there is technological deficiency especially in terms of integrating geospatial with any system that has the ability to print out all the acquired information accurately. This document is very important and acts as information dissemination tool for various agencies in order to plan their strategies in the future (Thymianidis *et al.*, 2012).

This article presents recent advancement and challenges of additive manufacturing (AM) for geospatial images solution. In order to produce the image solution via additive manufacturing, the geospatial image needs to be converted into drawing data without any major changes. It is necessary in order to preserve the originality of the geospatial image. Then, these images can be printed out based on the actual color, contour and mapping condition. The main challenge of this approach is to secure the printing accuracy, precision and tolerance.

Revolution of 3D Printing in Additive Manufacturing

Every technology has their chronological history of development. Additive manufacturing and 3D printing began with the initial commercialization of stereo lithography (SL) in 1987. It can be divided into three developments phases which are the past, current and future. The novel ability of additive manufacturing procedure is the ability to create complex models and irregular shapes with multi-material properties. It has been utilized in various applications such as in automotive, aerospace, defense, restoration, consumer products, architecture, food and many more. The focus of this study is to better understand the recent advanced technology of additive manufacturing for geospatial images data. The importance of geospatial images is to facilitate people who cannot read geographical data in order to extract geospatial information such as politicians, soldiers and many more. This article also describes about the development of 3D printing in converting geospatial data into physical models (Paritala *et al.*, 2017).

Additive manufacturing, also known as layered manufacturing (3D printing, direct digital manufacturing) is an advanced manufacturing technique that replaces process-based job shop operations with product model driven operations based on a 3D CAD model (Holmström *et al.*, 2016). The 3D geometry is converted into a series of motion commands for an additive manufacturing machine by a class of geometric algorithms known as slicers. It starts with digital thread for additive manufacturing (DTAM), a single and seamless of data (Cotteleer *et al.*, 2016) originating from a CAD model in the design environment and moving towards a pre-processing environment to produce the distinct tool paths of making up each layer (Rejeski *et al.*, 2018). It follows by manufacturing environment to fabricate the complex shapes (Steuben *et al.*, 2016). This process is well aligned with additive manufacturing data management, an approach to maintain complex relationship across its lifecycle between the part geometry, material and individual processes to create the final product, known as additive manufacturing Informatics (Mies *et al.*, 2016; Biswal, 2017).

Since 1980s, this innovation showed rapid progression particularly in developed nations. It started in 1987 with the introduction of once well-known SLA (Stereo Lithography Apparatus) 250 machine, which is the main monetary accessible of additive manufacturing framework system in the world. A year later, the first-generation acrylate resin was first commercialized. Japan's NTT Data CMET and Sony/D-MEC commercialized their versions of stereo lithography apparatus, and Asahi Denka Kogyo introduced the first epoxy resin for CMET SL machine. In 1990, German Electro Optical Systems (EOS) sold their first stereo lithography machine namely Stereo and Quadrax presented the Mark 1000 SL system, which used visible light resin (Deshpande and Hsu, 2018). A year later, three additive manufacturing technologies namely fused deposition modeling (FDM) from Stratasys, solid

ground curing (SGC) from Cubital and laminated object manufacturing (LOM) from Helisys were first commercialized. Later on, in 1992, Teijin Seiki introduced Solifrom stereo lithography system and Allied Signal introduced Vinyether Elastomer resin products for SL. In 1993, 3D Systems and Ciba commercialized their first epoxy resin products and proceeded by the commercialization of ModelMaker or Sanders Prototype by Japanese and European companies in 1994. During the same year, Kira Corp commercialized Japan's first non-stereo lithography system called Solid Centre and German's Fockele & Schwarze (F&S) introduced a machine called EOSINT, which was based on laser-sintering technology.

In 1995, Japan's Ushio or currently known as Unirapid Inc sold its first stereo lithography machine. A year after that, Stratasys commercialized Genisys machine, which used an extrusion process that was similar to FDM, Z Corp. launched its Z402 3D printer, which was based primarily on concept modeling and BPM Technology commercially sold Personal Modeler 2100. In 1997, Systems Corp. Company developed a process called laser additive manufacturing (LAM) and Ciba purchased the exactomer resin business from Allied Signal. In 1998, Beijing Yinhua Laser Rapid Prototype Making & Mould Technology Co. Ltd offered similar technology as FDM and other additive processes. Also, Autostrade started introducing its E-DARTS stereo lithography system to companies in Japan and Thermojet 3D introduced faster and less expensive version of Actua 2100.

Innovation of 3D printer became highly sophisticated in year 2000s. LOM machine was produced in Tokyo by Toyoda Machine Company, Sanders Design International announced the development of a machine named Rapid Tool Maker (RTM) and Stratasys introduced a prodigy machine that produced parts in ABS plastic by using FDM technology. In 2001, Objet Geometries began to ship a beta version of its Quadra 3D printer, which combines ultrasonic welding and CNC machining to produce aluminum parts. In the same year, Generis GmbH of Germany commercialized a system used an inkjet-printing technique. Also, Idaho National Engineering and Environmental Laboratory (INEEL) developed a technique for rapid solidification process (RSP).

The technology of lamination, laser sintering, stereo lithography and plaster sintering (similar to FDM) were commercialized by Wuhan Binhu Mechanical & Electrical Co. Ltd of China in 2002. A year later, Z Corp. introduced its ZPrinter 310 system. Meanwhile, North America announced EOSINT laser-sintering, Sony Precision Technology America in US began to market the Sony stereo lithography machines, Envisiontec introduced the Vanquish photopolymer-based system, DSM Somos introduced new resins of SLA/SLS and ProMetal division of Ex One (currently known as Extrude Hone) introduced the small RX-1 metal-based machine (Deshpande and Hsu, 2018). In year 2005, Z Corp. released its latest color 3D-printing system, the Spectrum Z510, 3D Systems unveiled the Sinterstation Pro, a large frame laser-sintering machine with part breakout, powder handling and recycling and Stratasys launched its RedEye RPM and PolyJet machines. On the other hand, Z Corp. commercialized a large powder-based system originally developed based on 3DP technology. In 2006, 3D Systems announced InVision DP (dental professional) system, which includes an InVision 3D printer and 3D scanner for dental market and Somos unveiled NanoTool, a nanoparticle-filled photopolymer for stereo lithography with high heat-resistance capabilities. Two companies introduced new invention of 3D printer in 2007. 3D Systems introduced the V-Flash 3D printer that used film transfer and flash-imaging technology and Z Corp. introduced ZPrinter 450, the first color 3D printer that removed and recycled the loosed powder. In 2008, Stratasys commercialized the FDM 360 to replace Vantage machine and 3D Systems began shipped the first V-Flash desktop modeler. EOS of Germany introduced its high-elongation polyimide PrimePart DC for plastic sintering and Stainless Ph1 for its direct metal laser-sintering platforms. England MTT released a larger selective laser-melting machine, the SLM 250–300, built with automated powder handling and recycling. Mcor Technologies of Ireland officially launched its Matrix 3D printer and Huntsman Advanced Materials introduced the Araldite Digitalis.

In 2009, Dimension 3D Printing Group of Stratasys introduced the uPrint Personal Printer that used the ABS, Objet Geometries announced it Connex 350 system that used ePlyJet Matrix technology to print multiple digital materials with different properties, Lawrenceburg, Tennessee launched its 3D prototype parts service bureau and EuroMold of EOS announced two new plastic laser sintering machines, namely EOSNT P395 and EOSINT P760. A year later, Stratasys and HP signed an agreement for Stratasys to manufacture an exclusive line of HP-branded 3D printers, Optomec released its Aerosol Jet Display Lab System for touch screens and display applications by using direct-write technology and Z Corp. announced a distribution agreement with Envisiontec for its Ultra DLP based machine. Delta Micro Factory Inc. in Beijing, China introduced its extrusion-based portable personal UP! 3D printer and Spanish research centre, IQS announced two new Hydroxyapatite (HA) formulations that can be used in 3D printers. In 2011, MTT Technologies Ltd. (UK) and SLM Solutions GmbH (German) produced a selective laser melting equipment. CRP Technology from Italy introduced carbon-fiber-filled material which is Window XT 2.0 that has greater strength and elongation. In India, 3D Systems acquired Sycode Software Solutions that developed plug-ins for CAD system and Print 3D, which has additive manufacturing quoting plug-in for CAD software. During the same period of time, Object released VeroClear, which was an ABS-like digital, clear and transparent material and New Mexico released Optomec as a new wide-area Aerosol Jet print head to print 3D parts for electronic products.

In 2012, MakerBot in New York released the MakerBot Replicator with larger build volume than its predecessor and EasyClad in France introduced the MAGIC LF600 large-frame additive manufacturing machine. BumpyPhoto in Oregon launched 3D color printed photo relief, Solidscape introduce the 3Z line of high-precision wax 3D printers and Autodesk in California announced a collaboration to create the first 3D bio-printing software. A year later, Arcam in Sweden released its Arcam Q10 machine and 3D Systems acquired the service provider, Rapid Product Development.

Additive manufacturing, especially 3D printing has gone through a lot of different phases of development for more than 30 years. It is an innovative approach of making parts by simply adding the raw materials. It changes the designing, assembling and manufacturing of mass production indistinguishable items to low-volume, innovative, customized and manageable items. One superior characteristic of additive manufacturing is the ability to create intricate shapes with multi-material properties and complex architectures. It can be applied in various fields such as automotive, aerospace, defense, medical, consumer products, food and many more.

Applications of Additive Manufacturing

In automotive industry, the application of additive manufacturing is quite comprehensive. The usage of this safe, smart and sustainable products can be seen in LM3D 3D printed car series from Local Motors, 3D printing of Audi spare parts, new suspension development for Blade, 3D printed supercar by Divergent Microfactories, racing car parts for William F1 team and thumb tool for BMW. The benefits of additive manufacturing in automotive industry can be explained in terms of cutting the time especially during the parts development process and upgrading the quality of the design. These attributes can be achieved with the ability of additive manufacturing in customizing the tooling with reduced cost, producing complex design with decreased weight and reducing assembly and production cost. **Fig. 1** shows the product of additive manufacturing based on automotive application.

Additive manufacturing technologies are also widely used in aerospace and defense industries, which are well-known for their stringent design requirements. The ability of additive manufacturing to manufacture lightweight parts with geometrical and material complexities is very valuable. This technology has been applied in every step of manufacturing process, starts from design concept to end life repairs. Electron Beam Technology (EBM) has been utilized in fabrication process of complex aviation parts. **Fig. 2** shows the aviation part using additive manufacturing system.

The adaptability of 3D printing method with the practicality of producing cost-effective has reformed this technology into new ventures such as kitchenware to nourishment fabrication. 3D printing also incorporates a synthetic chemical design and creates the product by utilizing supercomputers for the purpose of examining the mixture of few substances to produce and assemble of novel chemical compound ([Kurzrock and Stewart, 2016](#)). There is other various application of 3D printing such as in the field of synthetic chemistry for fluidic reactor and reactionware for chemical synthesis. The ability of additive manufacturing processes to manufacture process-dependent of material microstructures demonstrates the flexibility of the technology to be accepted worldwide ([Yalcinkaya and Singh, 2015](#)). **Fig. 3** shows the example of drug printing using additive manufacturing.

In addition to the extensive use of 3D printing in automotive, aerospace and chemical industries, it proves to be beneficial to medical service industry. This industry has seen major transformation especially in biopharmaceuticals, restorative innovation and surgical methods. additive manufacturing is one of the main technology that contributes to this rapid advancement particularly in surgical and diagnostic aids, prosthetic development and tissue engineering. Current research in therapeutic field has fortified the capacity of creating many-sided shapes in the biomedical field such as craniofacial, dental prosthetics and tissue engineering ([Ota et al., 2016](#)).

In food industry, the computerization of manufacturing process increases the productivity and improves quality of products as the food processing involves labor intensive and repetitive operation. The introduction of food printing or digital food manufacturing process allows food to be customized into several colors, shapes, flavors and textures ([Sun et al., 2015](#)). One of the technology that has been widely used in food industry is 3D Foodini printer produced by Natural Machine. This printer can print various sweet and appetizing dishes such as pizza, spaghetti, mini burgers, chocolate, etc.

Current Technology of Additive Manufacturing

Additive manufacturing (AM) processes can be structured from multiple point of views. It is due to the variability of the instrument and material used, high potential to be further improved and their application towards specific industries. additive

Fig. 2 Aviation parts using additive manufacturing system. Reproduced from Coykendall, J., Cotteleer, M., Holdowsky, J., Mahto, M., 2014. 3D opportunity in aerospace and defense. In: Additive Manufacturing Takes Flight. Deloitte University Press, pp. 1–28.

Fig. 3 Drug printing. Retrieved: <https://medtechboston.medstro.com>.

manufacturing can be divided into two categories which are Rapid Manufacturing (RM) and Rapid Prototyping (RP). RM uses different types of materials which can be classified into four material categories, namely polymers, metal, ceramic and composite (Levy *et al.*, 2003).

There are various advantages of using additive manufacturing technology such as the net shape process. It means that less crude or raw materials utilization, which can be up to 25 times less machining process or ability to produce hard to machine products or the combination of both. The net shape ability helps making complex parts with a single step by eliminating multiple operation such as welding and brazing. Moreover, additive manufacturing technology can print a light weight structure, either by the utilization of grid design or by planning a specific placement of the materials without any other constraints. It also has the capability of producing parts which has complex inside channels and multiple sections in one operation. Fig. 4 shows the additive manufacturing processes with large material categories.

The printing rate for each machine is different due to the size, material and type of additive manufacturing used. However, the printing process is generally the same. Normally, low-cost printers utilize plastic fibers such as ABS or PLA with thickness of

Fig. 4 Additive manufacturing processes with large material categories.

1.75 or 3 mm. It is comparable to hand-work of producing parts by using plywood or acrylic. For open source printers, the software is free such as 3D design apps, slicers, printer control apps and many more. One interesting point to be mentioned is that few printers are technically reproduce themselves, as the fact that some of their components are made from printed parts (Abbott *et al.*, 2018).

Geospatial Images

Geospatial data, or in other word “geographic data” or “spatial data” can be characterized as information represents the location, size and shape of all objects on earth (Lee and Kang, 2015). There are many things that can be considered as geospatial data such as transportation system, property limits, coastlines, aerial imagery and terrain models. Safeguarding geospatial data proves to be a challenge which is similar as protecting all other types of advanced data. There are various technologies that can be used in order to acquire the geospatial data. Nowadays, geospatial data can be obtained by using GPS-enable cellphone and stores in geographic information system (GIS). This system allows the manipulation or visualization of data such as one selected area can be represented in latitude and longitude coordinates, or even a street location. Geospatial information can include various data features such as highway intersection, office structure and political boundaries.

GIS software or Geographic Information Software is a project files consisting of perplexing computerized records that tie together wide assortment of segments, which includes data, instructions on how the data will be displayed, metadata, data models, scripts and other subordinated parts (Eyers and Potter, 2017; Fernandez-Palacios *et al.*, 2017). These documents are blend of information data, which are displayed in a custom-made way that includes grouping, symbolization and annotation based upon the data content. These data can be viewed as maps, charts or tables or some combination of those elements. There are some required processes to render these contents which show the importance of project files, the software that supports the project files, related parts including programming additional items (software add-ons) or extensions and genuine information. The utilization of programming is required for these many-sided qualities of project files to prevent catastrophic failure in the future (Gausemeier *et al.*, 2011).

The development of location-based information technology is the main driver of geospatial digital asset management. Potential industry that can fully utilized these geographical information is insurance industry, especially in determining location or environment that can be exposed to hazardous elements. By exploiting the high-end technology such as multispectral satellite opens up the possibility of acquiring earth perception information, which proves to be valuable for geospatial data analysis. The accessibility of these information expands the usefulness of geospatial technology into new territories such as disaster management, global security and many more. Furthermore, the significance of geospatial technology especially in digital imaginary and its associated products is acknowledged by the public. In 2003, a highly visible conference by GeoIntel appeared to proclaim the importance of geospatial data in US and will generally perceive as an essential component in the commercial sector (Hare *et al.*, 2018).

In order to convert geospatial data to physical or 3D model, it requires a shapefile which comprises of at least three documents, namely a .shp file (feature geometry), a .shx file (list of element geometry) and a .dbf file (a database file that stores the characteristic data of the features). Additional files can be incorporated in this shapefile such as .prj (projection file), .xml (metadata file) and also .sbx and .sbn (index files). Shapefile format presents general guideline for today's standard and widely utilized. Other typical vector format that has been utilized for geospatial data especially in CAD environment is Autodesk DXF, which is a drawing exchange format. There are three stages to convert geospatial data to physical 3D model, which are the input, process and output. All stages are shown in Fig. 5.

Fig. 5 The procedure to implement geospatial to physical conditions.

Fig. 6 Flow chart for overall methodology.

The Challenges of Integrated Additive Manufacturing and Geospatial Images

Digital geographical data and geoprocessing have become rapidly important with the advancement of information technology, demanding solution of environmental problems, development of urban and rural planning, development of military strategy and many more (Levy *et al.*, 2003; Janee, 2009; Ghawana and Zlatanova, 2013; Chia and Wu, 2015; Evangelidis *et al.*, 2018). In Malaysia, the number of geospatial technology companies are increasing even though in slower rate. This geospatial technology refers to the technology that is used to acquire, manipulate and store geographical information. It integrates multiple systems such as GIS, GPS, remote sensing and many more. The purpose of a geospatial technology is to share location-based digital geo data that is usually available in public administration based on information technology (Groger and Plumer, 2012; Elberink *et al.*, 2013). Nowadays, due to the rapid changing of information related to the city planning for urban and rural development, and also for military defend strategies, geospatial information has higher demand. It proves to be more effective to get geo data for locations that cannot be tracked by humans.

All geospatial data or documents can be visualized by using digital image. But, most people unable to interpret the data accurately (Evans *et al.*, 2014). It is because, digital image is not representing the actual picture, but it only displays colorful digital bit image (Biljecki *et al.*, 2014). Therefore, in order to represent the data accurately, 3D technology is able to fulfill the demand.

Fig. 7 Flow chart of Phase 1.

But, this technology proves to be too costly. Furthermore, 3D technology to print geospatial data or images is relatively new in Malaysia and most companies send their geospatial data overseas for 3D printing process.

In this section, a new method of printing out geospatial images by using additive manufacturing approach in 3D model is presented. This method allows the integration of geospatial document and data to create 3D environment, which can be zoomed, rotated and viewed from different angles. By concentrating the effort of upgrading the existing additive manufacturing approach, 3D modeling will gain rapid improvement towards creating more realistic model such as urban and rural landscapes equipped with building or forest, topographic variations and location and many more at lower cost.

The flow chart for overall methodology of the solution is shown in [Fig. 6](#). This study is divided into four consecutive phases which starts from product design (Phase 1), development of machine (Phase 2), functionality and reliability (Phase 3) and market acceptance (Phase 4).

The product design phase is consisted of integrating geospatial data or document with additive manufacturing approach. It includes parameter study, parameter integration, parameter constraint and parameter change for different conditions which are before, current after the printing process. In this phase, benchmarking process is also performed by investigating relatively similar approach that has been used or studied in the past. It is also a mode of obtaining baseline and referenced data. The flow chart of product design is shown in [Fig. 7](#).

Phase 2 is focusing on the development of the machine, which includes the modification of existing machine and software development. The main objective is to define the required hardware, software, machine language and module of the additive manufacturing to be fully integrated with the geospatial 3D modeling. For the purpose of market acceptance, this new method of printing geospatial images in 3D modeling must fulfill the requirements established by OGC/ISO1-19128 Web Map Service (WMS) and ISO-19155 Geographic Information Standard. Both standards are used for global geospatial 3D modeling to design high resolution 3D model, which is reliable and conforming the actual landscape or contour. This development process consists of several stages, which are software integration between geospatial raw data or document with additive manufacturing tool, design specifications, design rules and development of 2D and 3D formatting. The flow chart of this phase is shown in [Fig. 8](#).

In printing the 3D modeling of geospatial images, quality is the most important criteria that needs to be accomplished when producing the final product. The quality of 3D modeling can be determined and evaluated based on the functionality and reliability tests of the product. Several test procedures are used such as the logical model test, spatial relationship, visualization, 3D object reconstruction, image texture extraction and image texture mapping. These proposed test procedures are necessary to ensure 3D modeling is accepted by the geospatial industry and adhering to the regulations imposed by international standards ([Fernandez-Palacios et al., 2017](#)).

The 3D modeling of geospatial images is very important for urban and rural planning and in military strategies. Therefore, the demand of this technology is expected to increase in near future especially in the emerging market by 2025. Evidently, there are many studies investigate and evaluate the effectiveness of the additive manufacturing tools to print out 3D modeling of geospatial images. Based on the studies, the utilization of additive manufacturing in geospatial technology is still in early stage. However, the demands are very high especially in United States and Asia. In Malaysia, the demand for geospatial technology comes from state and federal government for the purpose future planning. However, 3D modeling of geospatial images technology is still lacking. Because of that, the geospatial company in Malaysia needs to courier the raw data overseas in order to print them out. This lengthen process inevitably impacting the cost. Therefore, this 3D printer machine will have high demand in the future because of the acceptable high quality with much lower cost. Market acceptance study is needed in order to identify the product attributes and perception among Malaysians towards this technology for both short and long terms. In addition, the market acceptance is also a crucial factor in determining the preference, choice and required trade-offs in fulfilling future demands.

Fig. 8 Flow chart of Phase 2.

Conclusions

This article presents the recent advancement and challenges of additive manufacturing geospatial images solution integration. Basically, additive manufacturing technology shows a great potential to be used in various applications and industries like automotive, aerospace, defense, kitchenware, chemical, food processing and many more. By integrating the additive manufacturing and geospatial technology, the utilization can be infinite. The integrating technologies are totally embracing the new era which is fully supported in Industrial Revolution 4.0 (IR4.0), which is expected to be the future trend on how innovative technology works and delivering the product. This integration technologies have a lot of obstacles that need to be answered in future, and it is also provides opportunity of exploring new technological possibilities. To do that, this article is able to present the detailed procedures of integrating both additive manufacturing and geospatial technology through a structured development process.

Recycled Clothes With Polypropylene-Nanoclay for Industrial Product via Injection Molding

Mohd H Othman, Tun Hussein Onn University of Malaysia, Johor, Malaysia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Typical consumer tend to reuse their clothes through donation or throw away into landfill. Economic growth will increase consumerism, hence lead to more clothes to be used, posing a significant challenge towards waste management and environmental control (Gupta, 2012). One of the possible ways to decipher the reduction of carbon footprint of textiles and clothing sector is to recycle the textile process waste and also to recycle at the end-of-life of textile products. Detailed investigation of the possibilities, barriers, and challenges to recycle textile waste materials with relevant case studies have been discussed (Muthu *et al.*, 2012). Therefore, clothes recycling had become one of the option in order to reduce abundant of waste made from this product. Through recycling, the energy needed to make new products from natural materials could be reduced. For instance, in United Kingdom it was found that the reuse of 1 tons of polyester garments only uses 1.8% of the energy required for manufacture of goods from virgin materials (Woolridge *et al.*, 2006).

In term of polymers, polypropylene was quoted as a semi-crystalline plastic which is tough, stiff, weight to cost effective, balance of strength, modulus and resistance towards creep (Chanda and Roy, 2008). Thus, polypropylene was proposed as thermoplastic composite matrix (Jeencham *et al.*, 2014). As for the filler for composite matrix, clay was chosen to provide a better physical and chemical environment for the polymer (Ramsaroop *et al.*, 2010). A combination of polypropylene-nanoclay had increased more researchers to perform more investigation about the improved properties, the effect of clay content as well as the cost effective-additive utilization (Othman *et al.*, 2014b). Several research have carried out an optimization process towards polypropylene-nanoclay based material at many applications, such as snap fit samples (Othman *et al.*, 2014a), shrinkage and warpage (Othman *et al.*, 2017) and melt flow index (Othman *et al.*, 2018b).

As for exploiting the recycled polymer, a review had been made by Hamad *et al.* (2013), whereby polymers such as polylactic acid (PLA), polyvinyl chloride (PVC), polypropylene (PP), polyethylene (PE), polystyrene (PS), acrylonitrile butadiene styrene (ABS), polyethylene terephthalate (PET) and polyamide (PA) could be recycled through reused, chemical and mechanical recycling. In this article, mechanical recycling through injection molding was chosen because it is a similar process in industry and widely used. Since injection molding is one of the preferred manufacturing process for plastics, then the recycled material that could go through injection molding again would be very beneficial for manufacturing industry. However, the major concern is about the degradation of the mechanical properties. Several studies have been conducted about the properties of the recycled polymer. Table 1 shows some of the findings related to polymer recycling.

Therefore, all of these findings have motivated the use of recycled clothing to be compounded with polypropylene-nanoclay matrix. Thus this compounding can be used as a secondary raw material in the manufacturing process, such as injection molding. By using this approach, the disposal of these clothes that can cause pollution to the environment can be reduced and the plastic manufacturing industries may benefit the applications of this new material in terms reducing the cost and consumption of raw materials.

Preparation of Recycled Clothes With Polypropylene-Nanoclay

To compound the recycled clothes with polypropylene-nanoclay, several processes have to be carried out. First, the clothes have to be shredded into small pieces. It is preferred to use the same clothes material. Then, the shredded used clothes were dried up to remove the moistures by using a drying machine. The recommended temperature was set between 90 and 100°C for 15–18 h. Then, the dried pieces of clothes need to be grind into fibers through grinding machine. These fibers were compounded with polypropylene and nanoclay through a twin screw extruder to make feedstock for injection molding. Polypropylene with 5 wt. % of nanoclay (PPNC-5 wt. %) and 15 wt. % of compatibilizer was used as the polymer matrix. The feedstock need to be crushed into pallets so that it can be injected by using injection molding machines to produce industrial product. The compound could be prepared with three different percentages which were 1%, 2% and 3% of fibers made from recycled clothes.

Properties of Recycled Clothes With Polypropylene-Nanoclay

In this article, injection molding was selected as an approach to recycled clothes into secondary raw material for manufacturing. Injection molding was selected since it is better compared to hot press machine because, injection molding using very high pressure, which can lead to mold better, with a strong pressure molding process to mold than others.

Table 1 Properties studies of recycled polymer

Authors	Recycled Polymer	Properties Studies
Evstatiev <i>et al.</i> (2002)	Poly (ethylene terephthalate)	Elastic modulus, tensile strength and impact strength
Mehat and Kamaruddin (2011)	Polypropylene	Flexural modulus
Rahimi <i>et al.</i> (2014)	Acrylonitrile butadiene styrene	Shrinkage, impact resistance, flexural strength and tensile properties

Fig. 2 Young's Modulus vs. Trials for each formulation. Edited from Othman, M.H., Muhammad, A.I., Hassan, S., 2018a. Investigation of clothes recycling as colouring agent for polypropylene-nanoclay nanocomposites. *International Journal of Technology and Engineering Studies* 4 (1), 1–6.

Fig. 3 Example of resin compound made from recycled clothes/polypropylene/nanoclay.

To quote one of the example of material properties for a compound of recycled clothes with polypropylene-nanoclay, the average values of Young Modulus have been summarized and the graph of Young's Modulus versus Trials have been displayed in [Fig. 1](#). Based on the results of tensile test, the highest average Young's Modulus value with the 502.104 MPa for 3% of recycled fiber from recycled clothes. As for the sample mixed with 1% fibers, it recorded the highest value of 491.244 MPa for Young's Modulus. According to [Fig. 1](#), the Young's Modulus value for polypropylene-nanoclay without fiber was lowest as compared with other samples ([Othman et al., 2018a](#)).

Before injection molding was performed, the length of injection-molded cavity was measured before it heat up. After that, the length of produced samples was measured, to analyze the shrinkage. The value of average shrinkage is exemplified in [Fig. 2](#) with the average value of 0.01482 mm. After ejection from the mold, the flashing and runner was removed from the sample. The reading of thickness was measured at 10 different places on the sample by using a micrometer screw gauge. For the maximum height of the sample, the reading was recorded using dial gauges. The value of average warpage is displayed in [Fig. 2](#) ([Othman et al., 2018a](#)). From this figure, it showed that the average warpage was 0.0332 mm. According to [Fig. 2](#), it can be assumed that the product of recycled clothes/polypropylene/nanoclay had a stable shrinkage but could produce variation on warpage values. Hence, more focus was needed to control the warpage value to reduce this defect during manufacturing process.

In present application, the coloring agent that were used in the plastic industries are the dyes and pigments. Both methods are substantially different and produce specific results. Dyes are defined as colorants that are (completely) soluble in a polymer at the processing temperature ([Müller, 2003](#)). In this study, innovation is carried out on recycled clothes as coloring agent for polypropylene injection molding process. As polymer synthetic materials, textile fiber extracted from recycled clothes have potential to be as coloring agent for plastic by compounding the fiber with polymers. As transforming recycled clothes into coloring agent for plastic, the issues of textile waste can be reduced. Undesirable clothes waste was unavoidable by-product in most apparel manufacturing process ([Bhatia et al., 2014](#)). [Fig. 3](#) shows the example of resin compound made from recycled clothes/polypropylene/nanoclay, whereby the colors of black, red and yellow were produced from the recycled clothes with similar colors.

As for the conclusion, it was proven that the approach to recycled clothes by using injection molding has been succeeded. The value of young's Modulus, for the samples recycled clothes (cotton fiber) has higher value compared to sample polypropylene-nanoclay. All the properties of recycled material can be clarified based on graph plotted after testing. The recycled clothes/polypropylene/nanoclay also have a good control on shrinkage. It can be also used as the coloring agent. Based on these findings, these compounded materials can be used in the application of industrial products such as plastic bottle, container, automotive component/cover and more. The outcome of this project should be beneficial in future of plastic manufacturing process; in terms reducing the cost and consumption of raw materials.

Renewability and Sustainability: Current Status and Future Prospects

Sayyad Z Qamar and Mahmoud Al-Kindi, Mechanical and Industrial Engineering Department, Sultan Qaboos University, Muscat, Oman

© 2020 Elsevier Inc. All rights reserved.

Introduction

With the continuing problems of deforestation, greenhouse emissions, ozone layer depletion, global warming, and overall environmental degradation, it looks like the world is running on a self-destruct mode. In the words of Terry Swearingen, 1997 winner of the Goldman Environmental Prize “we are living on this planet as if we had another one to go to.” Sustainability is one of the top most priorities today. Both recyclable and renewable resources (materials and energies) can help in making the planet better, safer, and greener, for current and future generations. To recycle means to transform waste products into new supplies or products. Resources that are renewable can be naturally and organically replenished over a given time period (Piletic, 2019). For a good “now,” and for a better “future,” it is important to understand and spread awareness about recyclable and renewable materials and energies that work in a sustainable manner. A native American proverb tells us that “we do not inherit the earth from our ancestors; we borrow it from our children.”

There are both positive and negative aspects to renewable and recyclable materials. Knowing how these two types of materials work is critical in trying to make our planet more sustainable. Which is a better option for sustainable living? Let us take logging of timber for the worldwide construction industry as an example. Should we opt for renewables and risk deforestation, or should we go for recyclables and face the hazard of increased pollution if the target of recycling is not met? An optimal solution is quite complex. Another option is ‘recyclable renewables,’ with the possibility of recycling our renewable products. Materials such as renewable plastics (made from cellulosic materials instead of petrochemicals) would be an excellent alternative, and may be a backbone of sustainability in the future (Piletic, 2019).

Some questions in this regard can be quite intriguing and thought-provoking. Let us look at a few more captivating ones. What is the difference between recyclable and recycled? When a material or product has the ability to be recycled, it is *recyclable*. A *recycled* article is made from materials that were part of something else. What is the difference between a circular economy and a linear economy? All over the world, a *linear economy* has been traditionally practiced, which can be summarized as ‘make, use, dispose.’ On the other hand, in a *circular economy*, products are reused instead of being disposed to extract maximum value. The sequence is now ‘make, use, dispose, recover, recycle.’ What is the difference between sustainable and renewable? *Sustainable* relates to a method or resource being maintained, while *renewable* refers to physical reuse of supplies. As an example, plastic is a renewable resource since it can be recycled; while the recycling of plastic is sustainable if the used plastic is recovered and undergoes a recycling process. What is the difference between renewable and sustainable resources? *Renewable resources* can be generated as fast as they are consumed. If this can be maintained, they are also *sustainable*. Again, plastics can be both renewable and sustainable if they are continually recovered and recycled to create new products (Coca-Cola-UK, 2017).

To have an idea of their intertwined nature, let us try to define and briefly discuss the three keywords: renewability, recycling, and sustainability.

Renewability

If an energy (or material) resource can be regenerated at the rate at which it is consumed, it is *renewable*. The word renewable is used mostly in the context of energy, but it can apply to anything that can be replenished. The term renewable is thus applicable to both materials and resources that are not completely depleted at their source, and can be produced at a pace to match the demand. In the energy sector, sources are either renewable (wind, solar, water, thermal) or non-renewable (coal, oil, gas). As for materials, most of the renewable ones are natural (timber, bamboo, cotton, hemp, etc). However, man-made materials such as plastics become renewable through recycling (Coca-Cola-UK, 2017).

If disposed of properly, plastic can successfully go through the three stages of recovery, recycling, and reuse. This can be in the form of the original material (new packaging or can), or as a new product (such as fibers or fabric). So plastic possesses *renewability*, and it is a renewable material. It is reported that recycled plastic consumes about 60% less energy for production compared to new plastic. This helps in sustainability; the higher the recovery and recycling, the more sustainable the source plastic is (Wikipedia, 2019a).

Renewable resources are mostly natural, and they can be replenished, so the portion depleted by consumption is replaced. The mechanism can be natural reproduction or through human intervention. Natural renewable resources are an intrinsic part of our planet's environment and a major component of its ecosystem (Stead *et al.*, 2009). Apart from agricultural production, and renewable energy, water is also a renewable material. The condition is that its usage, treatment, and release are carefully monitored. If not, water would be a non-renewable resource at that locality. For instance, groundwater is generally taken out from an aquifer at a rate much higher than its rather slow natural recharge, making it a non-renewable resource (USGS, 2019). Desalination of seawater also makes water a renewable resource. However, its dependence on energy derived from fossil fuels needs to be reduced for it to be completely renewable (Coleridge, 2008).

Increasing pollution is a major concern for water resources. According to an estimate, at least 22% of water is used by industries the world over (WBSCD, 2012). Bulk of these industrial users are hydroelectric dams, thermoelectric power plants (water as coolant), refineries for oil and mineral ore (water in chemical processes), and a host of manufacturing and chemical plants (water as a solvent). Without efficient chemical treatment, it would lead to severe environment damage and resource depletion (making water a major non-renewable resource).

Sustainable agriculture, as mentioned above, is an important factor in renewability. Coined by the Australian agricultural scientist Gordon McClymont (Rural Science Graduates Association, 2013), it means “an integrated system of plant and animal production practices having a site-specific application that will last over the long term” (Gold, 2009). Expansion of agricultural land reduces biodiversity and contributes to deforestation. The United Nations (UN) Food and Agriculture Organization (FAO) has estimated that farmland will be increasingly lost to industrial and urban development in the coming years. Reclamation of wetlands, and conversion of forest to cultivated land will happen simultaneously, leading to the loss of biodiversity and higher amount of soil erosion (FAO, 2003). Agricultural practices are perhaps the single largest cause for the global increase in soil erosion (Committee on 21st Century Systems Agriculture, 2010). At an estimate, more than a thousand million tons of soil are eroded each year only in the southern part of Africa. Some experts claim that farm yields will be reduced by half within 30–50 years if the current rates of soil erosion continue (South Africa CEP, 2013). Conscious and sustained efforts towards renewability are essential.

Air is one of the primary renewable resources, and it self-replenishes through natural processes such as the nitrogen cycle. All living organisms need oxygen, nitrogen and carbon in a direct or indirect manner, and many other gases. With the ever increasing amount of smog and pollution, this resource is becoming more and more toxic, and is also contributing to global warming. Increased and focused efforts towards renewability of the earth’s atmosphere are an imminent requirement.

Recycling

Recycling is the practice of reusing things that would otherwise be thrown away as waste. It is the process of converting trash materials into new materials and items. In conventional waste disposal, materials and equipment usually end up in a landfill. Recycling, on the other hand, can prevent the waste of potentially useful materials and reduce the consumption of fresh raw materials. This in turn reduces energy usage, air pollution (from incineration), and water pollution (from landfilling). In short, through recycling, rejected materials can be recovered for reuse, helping in lowering greenhouse gas emissions, and thus improving the environment and helping sustainability (Wikipedia, 2019b).

One variation of recycling is *upcycling*, which means adding value to an item so that it can be reused. The other type is called *downcycling*, which is the process of breaking down a product material into its components or elements, with the intent of reusing anything that can be salvaged. The third subclass of *precycling* is a new approach; the idea is to avoid procurement of “unnecessary” items that would have to be recycled in the future, or will be totally wasted. *E-cycling* is a rather new term, referring to the practice of reusing electronic components rather than dumping them at the end of their useful life (Wigmore and Rouse, 2019).

There are various materials that can be recycled, including many types of glasses, paper, cardboard, metals and alloys, plastics, rubbers and tyres, textile products, and electronic components and devices. Composting or other types of salvaging of biodegradable waste (food, garden, or agricultural waste) also comes under recycling. Materials that have to be recycled can be directly deposited at specific collection centers, or can be picked up from domestic or commercial waste bins, and then sorted, cleaned, and reprocessed into new materials, which can be later manufactured into same or different products (Murphy *et al.*, 1993).

There are various standards concerning the process and practice of recycling (Gopalakrishna and Reddy, 2018; Gencer, 2016). Two of the more important ones are ISO 15270:2008 (dealing with plastics waste) and ISO 14001:2015 (regarding control of environmental management for recycling practices).

Sustainability

If a process or state is *sustainable*, it can be maintained at a desired level for as long as it is required. According to the Brundtland Commission (United Nations, 1987), sustainable development “meets the needs of the present without compromising the ability of future generations to meet their own needs.” One dictionary defines *sustainability* as the avoidance of the depletion of natural resources in order to maintain an ecological balance. Sustainable development requires a balance between local and global efforts, such that basic human necessities are met without damaging the natural environment (Kates *et al.*, 2005; IISD, 2019c). However, the term ‘sustainable development’ is itself paradoxical in the eyes of some authors (Williams and Millington, 2004), as development is inherently unsustainable.

Maintaining the health of the environment and the ecosystem is a necessity for the continued survival of humans and other species. Some of the more important means of containing negative human impact are eco-friendly chemical engineering, management of environmental resources, and environmental protection (Bakari, 2017). Sustainability can be thought of as the aim of achieving equilibrium in the human-ecosystem domain (homeostasis). Consequently, sustainable development is a combination of holistic approach and temporal processes that can help us attain the target of sustainability (Shaker, 2015). Though sustainability is a very popular buzz word, the actual possibility that the human civilization will achieve environmental sustainability remains questionable. Climate change, environmental decay, population growth, overconsumption, and the race for uncontained economic growth are a few of the culpable factors (Worldwatch Institute, 2013).

Working towards a sustainable environment also entails a social challenge. It requires changes in national and international legislation, transportation and urban planning, supply chain management, consumer habits and lifestyles, etc (Madiati *et al.*, 2018). Improving of sustainability can be done in many ways: restructuring of living conditions (eco-friendly and sustainable villages, municipalities, etc); reevaluation of economic segments (green building, permaculture, sustainable agriculture); new work practices (ecological architecture); developments in science and technology (renewable energy, green technologies, and sustainable nuclear power); improving flexibility and reversibility in engineering design, (Fawcett *et al.*, 2012; Zhang and Babovic, 2012) and reshaping of individual and group lifestyles targeted at conservation of natural resources (Black and Cherrier, 2010).

The concept of sustainability is composed of three pillars: economic, environmental, and social (Capra, 2015; Scott, 2009); also known informally as the three p's: profits, planet and people. Culture, technology, and politics are considered to be the sub-domains of sustainable development (Magee *et al.*, 2013). Three main goals of sustainable development were agreed upon in the 2005 World Summit on Social Development (UNGA, 2005). These were economic development, social development, and environmental protection. The three pillars are not mutually exclusive, but are inter-dependent, and each can only co-exist with the others (Morelli, 2011). Some experts have added a forth pillar of 'future generations,' highlighting the long-term planning needed for sustainability (Waite, 2013).

Sustainability and the Various R's

According to one study, over 230 million tons of trash go to landfills per year only in the USA. Another study estimated that only 25%–30% of this waste is recycled (Annenberg Learner, 2019). To overcome this increasing problem, various recyclability and sustainability strategies (3R, 4R, 6R) have been proposed and are being promoted, 3R being the most popular.

The 3 R's: Reduce, Reuse, Recycle

The 3R policy (reduce, reuse, recycle) is the most well-known sustainability drive. It is sometimes also called the "waste hierarchy." It is the actions that should be taken, in the order of priority, to reduce the amount of waste generated, and to improve waste management efforts. The target is to bring about a small change in everyone's lifestyle, so that the amount of waste going into landfills is decreased, and the carbon footprint of human beings is reduced. This will help in the conservation of natural resources (materials and energy) and landfill space, and also generate economic savings in terms of money used currently for disposal of wastes in landfills. Putting up the site for a new landfill is becoming more difficult and expensive due to environmental regulations and public opinion.

The first 'R' is *reduce*, the idea of reducing what is produced and what is consumed. The logic is simple: if waste is reduced, then there is less to recycle or reuse. There are three basic questions that need to be assessed. First; can this function be done by using something else? Using the same thing for multiple tasks is an important first step towards reduction. Second; is it something that must be done this way? A large amount of waste material comes from disposable items. Third; is this item really a part of something that is necessary for your life? It is important to ensure that what we consume, or keep as an item to be used some day, actually matches the reality of potential opportunity in our lives (Conserve Energy Future, 2019).

The second R (*reuse*) is again very simple; exactly what it means. Learning to re-use most of our possessions, or using them for a different purpose than initially intended, is another essential in waste hierarchy. One of the best examples today is the modular construction of homes and office buildings, using rejected shipping containers. And if you absolutely do not want an item any more, and it is still usable, it can be donated to others. Some prime examples are old books, old clothes, old electric equipment and rechargeable batteries, etc (Conserve Energy Future, 2019).

The third R of *recycling* is the last stage of the waste hierarchy. After recycling, the item will be transformed again into a raw material that can be used to produce the same or a different new item. There are a lot of materials on earth that can be recycled, and yet it is not a common practice. First, society needs to learn as to what products can be recycled. Second, more efforts are needed in separation and collection of recyclable waste. Third, more progress needs to be made in uniting recycling plants with industries that can process the waste material (Conserve Energy Future, 2019).

The 4 R's: Reduction, Reuse, Recycling, and Recovery

Analyzing a number of the available waste prevention techniques, one group modified the 3R strategy to the so-called 4 R's of "reduction, reuse, recycling, and recovery." More and more businesses today are faced with stricter environmental regulations, public pressure, shortage of landfills, and demand for higher resource efficiency. Many companies are therefore changing their approach from 'waste treatment' to 'waste prevention.' As compared to organizations that focus only on the 3 R's in resolving waste management issues, more innovative companies are adopting 4R solutions being generated as an outcome of industry benchmarking or technological breakthroughs (IISD, 2019a,b).

The approach can be summarized as follows. If possible, waste *reduction* is the first option. If waste is produced, maximum effort should be made to *reuse* it, if practically feasible. *Recycling* is the third step in waste management, which obviously helps in conservation of resources and reduction of wastes. However, waste collection and recycling entail significant economic and environmental costs. That is why, recycling should only be looked into if the waste cannot be reduced or reused. As a further step, it is possible sometimes to *recover* materials or energy from waste that cannot be reduced, reused, or recycled (IISD, 2019a,b).

Empirical studies assert that through the practice of waste prevention, reuse, recycling, and environmentally conscious purchasing, businesses can reduce costs and increase profits. These cost savings include lower costs of waste disposal, waste treatment, energy usage, materials and supplies, regulatory compliance, and storage; and recovery of cost through sale of recyclable materials, and sales of 4R technologies (IISD, 2019a,b).

The 6 R's: Reinvent/Rethink, Refuse, Reduce, Reuse/Repair, Recycle, Replace/Rebuy

The 6R initiative for sustainability is a social drive to motivate and train common consumers to make recycling and sustainability a part of their daily routine. The 6 R's are reinvent/rethink, refuse, reduce, reuse/repair, recycle, replace/rebuy (Alatervo, 2018). *Rethink/reinvent* asks everyone to reconsider and question their daily consumption habits. Do we really need all the things we consume? Can some of these be recycled? *Refuse* means to make a conscious effort to not generate waste, as much as possible. *Reduce* hints at making daily-life decisions that decrease the amount of trash generated. Through buying only what we need, avoiding impulse shopping, and not purchasing more than the amount needed, we can reduce the amount of materials, toxins and waste sent to landfills. The idea of *reuse/repair* is to expand the usable lives of products. By using something again, or by finding new uses for an item, one can extend the product life, and reduce waste. The term *recycle* is rather obvious: at the end of a product's life, reclaim the raw materials for use in a new product. The common person just needs to separate out products such as aluminum cans and plastic (bottles, sheets, etc), and recycling companies can use them again. Recycled materials usually need less energy to process them into products compared to new materials (Recycling Revolution, 2019). Also, these items do not end up in the landfill, resulting in reduced air and water pollution. *Replace/rebuy* wants us to use, on a consistent basis, products made from recycled (or green) materials.

Renewability and Sustainability Practices

Legal reforms and subsidies at the government level play an important role in sustainability and in increasing the market share of renewables. One example is the Non-Fossil Fuel Obligations (NFFO) adopted in the United Kingdom, making it obligatory for the electricity distribution network operators to purchase electricity from nuclear power and renewable energy sectors. Scotland (Scottish Renewable Orders) and Northern Ireland (Northern Ireland Non-Fossil Fuel Obligation) also have similar legislative mechanisms in place. Renewable Energy Certificates (RECs) serve the same purpose in the United States. In Germany, their *Energiiewende* offers subsidies in the form of fed-in tariffs, resulting in increased use of renewable biomass in conventional fossil fuel plants (Clean Energy Wire, 2019).

Renewable Materials

Renewable materials are those which can be manufactured or generated quickly enough to keep pace with how fast they are used up. Non-renewable materials, including materials for energy sources, are those which take a long time to renew and are generally used faster than they can be regenerated. Renewable materials can be made from natural products or synthetically produced, and often include recycled products (Garvin, 2019).

Renewable materials are sustainable materials, which means, according to the Rutgers University Center for Sustainable Materials, these materials do not use up non-renewable resources. They can also be produced in high enough volume to be economically useful. Biopolymers are one such renewable material. A biopolymer is a naturally occurring polymer, such as carbohydrates and proteins. Some examples of biopolymers are cellulose, starch, collagen, soy protein and casein. These raw materials are abundant and biodegradable, and are used to make diverse products such as adhesives and cardboard (Garvin, 2019).

Rapidly renewable materials are plant-based materials that can be replenished within a period of ten years or less. Bamboo and cork are rapidly renewable materials used to create flooring materials for homes and office buildings. Bamboo is commonly used instead of woods such as oak, which is a relatively slow-growing tree. Although oak is technically a renewable resource, it takes many years for an oak tree to mature compared to bamboo (Garvin, 2019).

Biorenewable chemicals are produced through biological organisms, supplying feedstocks for the chemical industry (Nikolau et al., 2008). Instead of the petroleum-based carbon feedstocks that are currently used by the chemical industry, these chemicals are a good alternative as their production is based on solar-energy. There is a huge diversity of enzymes in biological organisms, and synthetic biology has a large capacity for altering these enzymes targeted at new chemical functions, paving the way for the chemical industry to use renewables (Garg et al., 2016; Leber and Da Silva, 2014).

Bioplastics are derived from renewable biomass sources, including vegetable fats and oils, lignin, corn starch, microbiota, etc (CORDIS, 2008). Thermoplastic starch is the most common type, while cellulose bioplastics, biopolyester, polylactic acid, and bio-derived polyethylene are some other forms. In comparison with production of plastics from petroleum derivatives, production and consumption of bioplastics is considered to be more sustainable. However, the issue that needs to be addressed is that petroleum is still used as an energy and materials source for the manufacturing of bioplastics. Compared to the global consumption of all flexible packaging (estimated at around 12.3 million tons) (NNFCC, 2010), worldwide production capacity for bioplastics is around 0.33 million ton (Plastics News, 2008).

One of the biggest construction activities, especially in developing countries, is building of roads and highways. *Bioasphalt* is an alternative type of asphalt, derived from non-petroleum based renewables, such as vegetable oil based waste, sugar, molasses and rice, and corn and potato starches. An asphalt that uses vegetable oil based binders as a source was patented in France in 2004 (Djumari *et al.*, 2017).

Renewable Energy

Renewable energy, as the name implies, is energy provided through renewable resources, which are naturally replenished at the rate at which they are being consumed. Its various forms are sunlight, wind, rain, tides, waves, geothermal heat, and biomass. Renewable energy may either replace or augment energy generated from fossil fuels, such as electricity generation, water heating, automobile fuels, etc (EIA, 2019a).

There are three main types of energy resources: fossil fuels, nuclear power, and renewable energies (Demirbas, 2000). Renewable energy is very attractive for three fundamental reasons. First, it is renewable; sources such as solar energy, wind energy, geothermal energy, marine energy, biomass energy, biofuels, and others can be used to produce energy over and over again (Rathore and Panwar, 1996). Second, these sources are capable of providing energy that is free of air pollutants and greenhouse gasses (Panwar *et al.*, 2011). Third, if developed properly, these technologies can harvest energy in a reliable, affordable, and environmentally sustainable way, especially in rural and small-scale energy sectors (Ravindranath and Hall, 1995). Various renewable energy technologies are already being used, while others are at various stages of development. Hussain *et al.* (2017) have discussed the state of the art for some emerging renewable energy technologies.

Biomass refers to biological material from living organisms, and is mostly plants or plant-derived materials. Sustainable harvesting and use of these renewable sources can reduce air pollution, soil contamination, habitat damage, and degradation of cultivable land (EIA, 2019b). There are six different sources of biomass energy: trash, wood, plants, waste, landfill gases, and alcohol based fuels. Biomass-based energy has been harnessed by humans for a very long time, such as burning of wood and wood-derived coal. Even today, wood is the largest source of biomass energy. Though a significant alternative for fossil energy, this low-tech use of biomass (contributing for more than 10% of world energy requirement) also causes indoor air pollution in developing nations, leading to a staggering 1.5–2.0 million deaths annually (Cheng, 2018).

Biofuels derive their energy from biological carbon fixation. These include fuels derived from biomass conversion, and also solid biomass, liquid fuels, and different types of biogases. For instance, in Brazil, bioethanol made from sugarcane is available in gas stations all over the country, in addition to regular gasoline. Bioethanol is a type of alcohol that is produced through the process of fermentation, using carbohydrates produced in sugar or starch crops such as corn, sugarcane, or switchgrass (Agarwal *et al.*, 2017).

Biodiesel is another biofuel, derived from vegetable oils and animal fats through the mechanism of transesterification. It is the most common biofuel used in Europe. When methane is produced by anaerobic digestion of organic material by anaerobes, the product is biogas. Typically, biogas refers to a mixture of gases that are produced when organic matter is broken down in the absence of oxygen. Apart from anaerobic digestion, the process can also be fermentation of biodegradable resources like manure, sewage, municipal waste, green waste, plant material, and crops. It is mostly methane and carbon dioxide, and may contain small amounts of hydrogen sulfide, moisture, and siloxanes (Knothe and Razon, 2017).

The other side of the coin should not be ignored. Rain forests are home to many species and organisms that are a source of food and other commodities for humans. From this viewpoint, biofuels may not be sustainable if their production causes deforestation.

Threats to Renewable Resources

Industrial development and technological growth, when not regulated in an eco-conscious manner, endangers all renewable resources. There must be a carefully thought out management system in place to avoid exceeding nature's capacity to replenish these sources. Life cycle assessment, at local and global levels, can provide a systematic method of evaluating renewability. World sustainability is intrinsically linked to renewability of natural resources and the environment (Mansson, 2016).

Sustainability mismanagement can take various forms. One is overfishing. National Geographic describes ocean over-fishing as "simply the taking of wildlife from the sea at rates too high for fished species to replace themselves" (National Geographic, 2013). Recently, cod stocks were severely overfished in the Atlantic, leading to abrupt collapse of cod population (Hui, 2006). Demand for tuna meat is increasing its overfishing, and endangering species such as bluefin tuna. Indirectly, overfishing is also resulting in the decline of penguin population, as humans and penguins compete over the same renewable resource (Science Daily, 2010). European Community and other world organizations are trying to bring in fishery regulations in order to protect certain species and prevent their extinction. The UN convention on the Law of the Sea treaty describes various aspects of overfishing (Council Regulation, 2002; UNC, 2012).

Another major threat to sustainability is deforestation. Forests are a major source of fuel and building material. Also, trees protect the environment by producing oxygen and by absorbing carbon dioxide (Mumoki, 2012). Destruction of rain forests (as in portions of Brazil) is a major root cause of climate change. Because of deforestation, CO₂ lingers in the atmosphere, and this accumulation forms a layer in the atmosphere that traps solar radiations. This trapped radiation generates heat, causing global warming. This is commonly known as the greenhouse effect (UNSG, 2001). Deforestation also disrupts the water cycle, decreasing the water content in soil, groundwater, and atmospheric moisture. Also, deforestation is a cause of reduction in soil cohesion, paving the way for soil erosion, flooding, and landslides (Rogge, 2012).

Sustainable Recycling

With the protection of natural resources and the earth's environment becoming a driving concern, many technologies have emerged in the last two decades for recycling of pollutants from water, air, and soil, and reprocessing of wastes (Corder *et al.*, 2015; Colling *et al.*, 2016). Meric *et al.* (2018) discuss various new environmental programs and projects that have been developed, both at national and international levels. These new projects and research studies have one common aim: sustainable technologies for recycling and reuse of various resources. Some of the more prominent ones are techniques for energy recovery from the organic portion of municipal solid wastes (Cesaro *et al.*, 2016), from food wastes (Karmee, 2016), from sludge left after wastewater treatment (Batstone *et al.*, 2015; Colmenar-Santos *et al.*, 2016), reclaiming of compost from solid waste organics (Cesaro *et al.*, 2015), and production of fertilizers from wastewater (Hukari *et al.*, 2016; Puchongkawarin *et al.*, 2015; Shepherd *et al.*, 2016). A few advanced treatment technologies based on the use of membranes have been developed and applied for recycling of urban (Bunani *et al.*, 2013) and industrial wastewaters (Zheng *et al.*, 2015).

Recycling of industrial wastes is another major avenue, either to be reused, or for manufacturing of new products. Some of these new technologies include recycling processes for automobiles (Li *et al.*, 2016), for rejected dry batteries (Lin and Chiu, 2015), for electronic wastes (Awasthi *et al.*, 2016), for waste automotive laminated glass through valorization of polyvinyl butyral (Swain *et al.*, 2015), for blast furnace sludge (Drobikova *et al.*, 2016), and for waste aggregates in concrete used for road pavement (Pasetto and Baldo, 2016). Though valorization of renewable energy sources is a ground-breaking technology in the recycling and reuse domain (Byrnes *et al.*, 2016; Sahoo, 2016), some researchers are of the opinion that is not totally green (Keramitsoglou *et al.*, 2016), and that it can cause negative environmental impact (Sokka *et al.*, 2016).

Renewable Technologies: Present and Future

With the passage of time, renewable energies are becoming more reliable and economically competitive in comparison with conventional energy sources. Until 2012, renewable energy formed about 19% of world energy consumption, but this share increased to 23.7% in 2014 (REN21, 2016). Some of the mainstream renewable energy methods currently in practice are hydropower, wind energy, solar energy, biomass energy, biofuels, and geothermal energy. Hussain *et al.* (2017) have reviewed and analyzed five state of the art renewable energy sources. These emerging technologies are either variants of the typically known energy sources (solar, wind, geothermal, biofuels, biomass, and hydro), or totally new processes. These include marine energy, concentrated solar photovoltaics (CSP), enhanced geothermal energy (EGE), cellulosic ethanol, and artificial photosynthesis (AP).

Marine/Ocean Energy

Marine energy, also known as *ocean energy*, is a highly attractive renewable energy resource. Sub-categories include wave power (wave energy), tidal power, tidal currents, salinity gradients, and temperature gradients. The source is almost infinite, three-quarters of our planet being oceans. Just wave energy has a potential comparable to the sum of nuclear and hydropower (Vining and Muetze, 2009). However, technological challenges have restricted the contribution of marine energy to only a minute proportion of global energy supply (Pelc and Fujita, 2002). For acceleration of marine energy initiatives, various regional governments have announced policies and incentives (Lewis *et al.*, 2011). According to a report published in 2015 by the executive committee of Ocean Energy Systems (OES), tidal power tops the list, followed by tidal currents, and then salinity gradient, as regards installed capacity. Only three countries agreed to the initial OES implementation agreement in 2011, while member countries were 23 by December 2015 (OES, 2014).

Wind that blows across the ocean is the main source of marine *wave energy* (Lewis *et al.*, 2011). Waves can transfer energy efficiently, and can travel long distances with few losses. Some ocean waves even gain energy through wind as they travel across open stretches (Clement and Cullen, 2002). Specialized converters can transform this wave energy into electricity. One major advantage of this form of marine energy is its spatial concentration in comparison with other sources of renewable energy (Titah-Benbouzid and Benbouzid, 2014).

Geographically, the United Kingdom possesses maximum potential for wave energy. Wave energy extraction techniques (WEET) can be classified in terms of location and power take-off (Titah-Benbouzid and Benbouzid, 2014). On the basis of location, WEETs can be divided into onshore, offshore, and near-shore categories. Categories based on power take-off are point absorber, attenuator, oscillating water column, oscillating wave surge converter, submerged pressure differential, and overlapping device, (Titah-Benbouzid and Benbouzid, 2014).

Tidal energy is generated due to the rise and fall of ocean waves, which is a result of rotational and gravitational forces between the earth, sun, and moon. Pattern of tidal currents is regular and predictable (IREA, 2014a). Size and timing of the tides is dependent upon geographical location, shape of the ocean bed, coriolis acceleration, and shape of the shoreline (Lewis *et al.*, 2011). Working principle of tidal power plants is not very different from hydal power plants. However, instead of flowing downhill, the wave masses move back and forth in sync with the tidal flow (Bryden *et al.*, 2006). The hydrokinetic turbines used for extraction of tidal energy can be of different categories: vertical axis turbines, horizontal axis turbines, venture effect turbines, or oscillating hydrofoils. Improvement in these technologies are being considered through the use of gears to allow different rotation speeds for the generator and the turbine, or by increasing the output by better employing the variable frequency generation (Lewis *et al.*, 2011).

Apart from near-shore tidal currents, other significant currents also flow in the oceans, known as ocean currents (Lewis *et al.*, 2011). These ocean currents are slower in rate, but are more consistent as compared to tidal currents. Also, ocean currents are unidirectional, while tidal currents can change direction in line with flood and ebb cycles (IREA, 2014a). Though basic principle of energy capture is the same, some of the infrastructure required for energy from ocean currents is different from tidal current energy extraction (Lewis *et al.*, 2011). Tidal current generators need to operate in both directions, while open-ocean turbines do not require this feature.

Energy derived from the concentration difference between two saline solutions is called *salinity gradient* power. The two possible energy extraction mechanisms are *stand-alone* (plant is located at the river-sea intersection) and *hybrid*. Hybrid processes work in tandem with a desalination or a wastewater treatment system (Scramesto *et al.*, 2009). Harnessing of energy in salinity gradient can be through pressure-retarded osmosis, reversed electro dialysis (RED), or other technologies, using the chemical potential between fresh (river) water and seawater. Also called osmotic power, this potential is captured as a pressure across a semi-permeable membrane (Lewis *et al.*, 2011). As with other osmosis-based technologies, the major issue is cost-effectiveness.

This chemical potential based process, known as pressure-retarded osmosis (PRO) or *osmotic power*, was developed in the 1970s (Loeb and Norman, 1975). In PRO, the salinity difference is between seawater and freshwater. The first prototype osmotic power plant went into operation at Tofte, near Oslo in Norway in 2009 (Van den Ende and Groeman, 2007). An alternate series of cation and anion exchange brings into contact the concentrated salt and freshwater. The reversed electro dialysis process generates electrical voltage across each membrane, utilizing the chemical potential difference (Loeb and Norman, 1975).

Ocean thermal energy conversion (OTEC) depends on solar energy. Due to sunlight falling on the seas, thermal energy is absorbed and stored in the upper layer. Energy is extracted through the OTEC cycle by using the temperature difference between the warm seawater at the ocean surface and the deeper (800–1000 m depth) cold seawater (Kim *et al.*, 2009). Warm seawater is used to produce vapors to drive a turbine, while cold water is used for condensation of vapors, ensuring that there is enough vapor pressure difference to drive the turbine (Yuan *et al.*, 2014). The three types of techniques of energy extraction in OTEC plants are open-cycle, closed-cycle, and hybrid-cycle (IREA, 2014b). In the open cycle, seawater is the working fluid, while it is ammonia, chlorofluorocarbon (CFC), or propane in closed cycle OTEC. Hybrid conversion, as the name implies, is a combination of open and closed cycle schemes (Lewis *et al.*, 2011). Theoretically, OTEC has the highest potential among the different ocean energy sources (IREA, 2014b). For a commercial-scale OTEC power plant to be operational, a minimum temperature difference of 20°C is required. The most optimal locations for OTECs are small islands, which need both power and fresh water. As with many other renewable energy sources, per unit cost is the main obstacle in making OTEC commercially viable.

Challenges and future prospects

For ocean energy to become a major contributor to world energy, innovative improvements are required in the technical, economic, social, environmental, and infrastructural areas. Overall, technical challenges are related to resources, devices, and array configurations. Among ocean energy extraction methods, ocean thermal energy, salinity gradient, and ocean current techniques are the least mature technologies, so they have the maximum potential for improvement. Having a very low environmental impact, and an almost endless source (oceans), policy makers and utility companies should make dedicated efforts to adopt these technologies. The most significant barrier is of course the high cost, significantly higher compared to other renewable energies (Lewis *et al.*, 2011). On the infrastructural side, the main challenges are related to grid issues and the supply chain, for marine energy to be integrated into wider energy networks.

Though ocean energy has a very high potential as a sustainable power source, there are some negatives as well. Marine life may be harmed or displaced, or the marine habitat may be damaged. The large structures housing marine energy extraction equipment and devices may reduce the size of commercial and passenger shipping channels. There will be a major concern of equipment damage through corrosion, and protection against sea storms may also pose a serious challenge.

Concentrated Solar Power/Photovoltaics

In *concentrated solar power* (CSP) technology, electricity is generated through heat produced by concentrating solar radiation on a small area. A combination of mirrors and/or lenses is used to reflect sunlight into a receiver. A primary circuit (thermal energy carrier) collects the heat, and this heat is used directly or thru a secondary circuit for turbine-based electricity generation (Muller-Steinhagen and Trieb, 2014). CSP systems can be equipped with a heat storage device to generate electricity even when skies are cloudy or after sunset. In comparison with wind and photovoltaics, CSP equipped with thermal storage can deliver a significantly higher capacity factor and dispatchability (Greenpeace, 2016).

A major component is the solar energy collector which absorbs and collects the incident solar radiation, and converts it into heat energy. A heat transfer fluid (HTF) that flows through the collector carries away the heat energy, serving as a link between the collector and the power generation system (Scramesto *et al.*, 2009). Obviously, as strong sunlight is a basic requirement, CSP is limited to hot and dry regions of the earth, including the Middle East, North Africa, South Africa, Australia, western US, and some parts of South America.

The first CSP power plant (with no thermal storage) was constructed in California in the 1984–1991 period (IEA-ETSAP and IRENA, 2013). However, there was no major interest in the technology due to abundance of low-cost fossil-fuel energy. By the year 2000, interest in CSP was revived due to energy shortages. A lot of research and development work has been done since then, focusing on collector types, materials, structures, and a variety of heat transport, storage, and electricity conversion systems

(Lorente *et al.*, 2011; Barlev *et al.*, 2011a,b). Major research effort during the last decade has been on increasing the efficiency of solar-to-electric energy conversion, and on making it economically more viable (Madaeni *et al.*, 2012).

Almost all CSP plants (with or without storage) are equipped with backup systems. Transfer fluids/liquids are heated thru fuel burners using fossil fuels, biogas, or solar energy. Because of these fuel-powered backups, as opposed to dependence on solar energy and thermal storage alone, production capacity of these plants can be maintained at a lower cost (Greenpeace, 2016). With these improvements, on-demand energy can be generated by combining CSP technologies with thermal storage. Integrating these systems with conventional energy sources (hybrid mode) can improve the performance of both.

Due to the declining investment and production costs, many new CSP plants have been constructed and commissioned since 2006 (IRENA, 2012). Currently, Spain is considered to be the largest producer of CSP electricity, while several projects are in the planning or construction phases in the USA and North Africa.

Parabolic trough (PT)

In the PT technology, concentration of sunlight is achieved thru heat receivers located on a focal line with parabolic mirrors. These receivers have a special coating that reduces infrared re-irradiation, thereby increasing the energy absorption. Convection type heat losses are minimized by positioning the receivers in a glass envelope under vacuum. Synthetic oil or molten salt is used as the heat transfer liquid, transporting heat to a steam generator for production of superheated steam which runs the turbine for production of electricity (IEA-ETSAP and IRENA, 2013). Heat from the heated fluid can be stored in a thermal storage system for times when sunlight is not available (Sioshansi and Denholm, 2010; US Department of Energy, 2014). PT plants typically generate 14–80 MW of electricity, and are mostly working in Spain and the US (IEA-ETSAP and IRENA, 2013). Total world capacity of installed PTs is around 850 MW. Some notable drawbacks of PT technology are high thermal losses, need for a good heat transfer medium, and requirement of long pipes to join the array and the steam generating plant.

Linear fresnel reflectors (LFR)

Similar to PT collectors, LFRs consist of a series of long, flat, and somewhat curved mirrors. Positioned at different angles, these mirrors can direct the sunlight to both sides of a fixed receiver, which is located a little above the main mirrors field. A single-axis tracking system, optimally installed at each mirror line, concentrates the sunlight on a fixed receiver. Purpose of a secondary reflector is to refocus any missed rays (IRENA, 2012). A newer version, called compact linear Fresnel reflectors (CLFRs), employs two equivalent receivers for every row of mirrors for minimum land usage, and a parabolic trough produces the required output (RENAC Renewables Academy, 2012).

The three operational LFR plants (to date) have been in production since 2008, and are located in California (USA), New South Wales (Australia), and Murcia (Spain). Capacities range from 1.4 to 5 MW (IEA-ETSAP and IRENA, 2013). Major advantages of this technology include readily available materials, lower manufacturing and installation costs (compared to parabolic troughs), direct generation of steam as water is the heat transfer liquid, possibility of hybrid operations, and lower heat transmission losses. On the undesirable side, performance, investment and operation costs are not commercially proven yet, and solar-to-electric efficiency (8%–10%) is lower than that of PT.

Parabolic dishes (PD)

PD collectors are also called solar dish collectors, wherein solar rays are concentrated at a focal point which is supported above the dish center. The dish and the receiver move in tandem to track the sun (Zhang *et al.*, 2013). The receiver can be a Stirling engine or a microturbine, eliminating the need for a heat transfer liquid and cooling water. This guarantees a larger heat-to-electricity conversion ratio. It is anticipated that commercial-scale production of PDs will make them competitive against larger solar thermal systems (Barlev *et al.*, 2011a,b). A 100 MW plant is being considered in Australia, while a few 10 kW or below projects are under development in Europe and USA.

Current energy cost of dish technologies is almost double of parabolic trough systems, so further technological development is definitely needed. Some key advantages of PD technology are 30% or higher conversion efficiency, no cooling requirement, suitability for remote and stand-alone operations, modular system, not limited to flat terrains, good manufacturability, and possibility of mass production due to the use of off-the-shelf existing parts. Major disadvantages include absence of large-scale commercial plants; lack of commercially proven investments, performance and operation costs; and problems in grid-connection.

Solar towers (ST)

ST technology uses various computer-assisted mirrors (heliostats) to track the sun over two axes, concentrating sunlight onto a single receiver. Mounted on the top of a central tower, the receiver utilizes a thermodynamic cycle driven by heat to produce electricity (IRENA, 2012). ST systems provide higher concentration in comparison with other CSP technologies. Steam, synthetic oil, and molten salts are the main heat transfer fluids. Working temperatures in the 250–1000°C can be reached, with proper combination of receiver design and working fluid.

Two 10 MW ST power plants were constructed in California in the 1980s and 1990s. However, both of them were later decommissioned. In recent years, various projects are under development in Spain, USA, Germany, and Israel. Some notable advantages of ST technology are higher efficiencies due to the potential of generating higher temperatures, more suited for dry cooling than PT, and ease of installation in hilly areas. On the other hand, commercially viable operation and consistent performance have not been proven yet.

Challenges and future prospects

It has been estimated that by 2020, total capacity of CSP could grow up to 30 GW in Europe, 50 GW in North America, 23 GW in Middle East and Africa, and that it could reach 337 GW worldwide by 2030 (US Department of Energy, 2014). For commercial viability and reliability, progress would have to be made on various frontiers. These include storage technologies, power blocks, cooling systems, transmission media for heat and electricity, and cost reduction. Potential areas for improvement in PTs and LFRs are solar field elements, replacement of thick glass sheet by less costly material, lower-cost alternatives for heat transfer liquids, and direct steam generators for PT to obtain higher temperatures (more efficiency). For PD and ST technologies, significant improvements could be made by replacement of water cooling with other mature technologies used in fossil fuels (air cooling, pressurized heat, etc), increasing the heat-to-power conversion ratio.

Enhanced Geothermal Energy

Heat energy that is stored in the earth's crust is known as *geothermal energy*. According to earth scientists, 20% of this energy is from the original formation of planet earth, while 80% comes from radioactive decay of different earth materials (Ziagos *et al.*, 2013). Temperature difference between the earth's core and its surface is called *geothermal gradient*, and is the source of the continuous conduction of heat energy from the core to the surface. Kewen *et al.* (2015) present a comparison between wind, solar, hydro, and geothermal energy, and conclude that geothermal energy has a potential which is equivalent to other major renewable energy technologies.

The conventional method of tapping geothermal energy is to locate the naturally occurring reservoirs of superheated steam and hot water. Tectonic and geological phenomena in that region contribute significantly in the sustainability of these naturally occurring reservoirs. That is why, these earlier geothermal technologies can be utilized only in those regions which are rich in natural reservoirs. A new approach, known as *enhanced geothermal system* (EGS), has been developed to overcome these limitations. Also known as *engineered geothermal energy* (EGE) or *hot dry rock* (HDR) energy, this technique is not dependent on the existence of natural geothermal reservoirs. There are two basic sub-categories of EGS techniques: augmentation of traditional geothermal systems by flooding extra fluid using a hydrothermal system, along with the naturally available ground water; and stimulated creation of enhanced permeability, all the way down to hot dry rock (HDR). Key advantages of EGS in comparison with conventional geothermal techniques are longer lifetime, higher productivity, location and sizing flexibility, increased resources, and various environmental benefits.

Performance of EGS power plants depends on various parameters, including reservoir and geological conditions, well drilling, and well completion. Drilling to a depth where rock temperature is high enough to justify total investments is an important consideration for extraction of geothermal energy. The next step is to develop an EGS reservoir in that region. Garman (2004) outlined five essential steps for the optimal construction an EGS reservoir. These are drilling of an injection well into hot basement rock having limited permeability and fluid content; injection of pressurized water for fracturing or reopening of existing fractures; continuous pumping of water to enlarge fractures and re-opening of previous fractures; drilling of a production well in the stimulated fracture area for water circulation aimed at heat extraction from the hot basement rock; and drilling of additional production wells for thermal energy extraction in large volumes from bigger hot basement rocks. Quality of the extracted geothermal energy is a function of temperature gradient, well depth, and rock porosity.

Some authors have investigated different aspects of enhanced geothermal energy, such as assessment of geothermal resource base, estimation of recoverable EGS, development history and current status of EGS related technologies, problems faced in design of subsurface systems, economic aspects of different drilling technologies (MIT, 2006; Blackwell *et al.*, 2006), concerns regarding EGS energy conversion systems, environmental impact assessment of EGS, and economic analysis and sustainability evaluation of EGS projects (Sanyal and Butler, 2005; Vuatez, 2000; Brown, 2000).

Some of the potential detrimental environmental impacts of geothermal energy projects are gaseous emissions, water pollution, land usage, induced seismicity, amount of water usage, stimulated landslides, small earthquakes, etc. Even then, geothermal energy poses much lower environmental hazards in comparison with conventional fossil-fuel and nuclear power units (MIT, 2006).

Challenges and future prospects

On top of economic viability, evaluation and testing of three critical issues is necessary for EGS power plants. First, a practical demonstration of a commercial scale reservoir that will be required for minimization of temperature decline in the reservoir. Second, sustained production from the reservoir. It has been estimated that fluids flowing at a temperature of 200°C and at a flow rate of 80 kg/s are needed to make the EGS power plant economically viable. However, to date, maximum flow rate actually achieved by EGS systems is only 25 kg/s. Third requirement is proof of repeatability; EGS reservoir performance needs to be replicated (Blackwell *et al.*, 2006). Continued judicious R&D investment is needed to make EGS an actual major contributor in pollution-free renewable energy provider.

Cellulosic Ethanol

Ethanol is a type of alcohol and is derived from different plant materials. Ethanol is now being used as an alternate liquid fuel in motor vehicles. The two major agricultural sources for ethanol production are sugarcane and corn starch. As both of these raw

materials are edible, there is a competition between human consumption and fuel production. Emerging non-conventional methods of producing ethanol use wood, grass, or other inedible plant parts as raw material. These new technologies utilize plant cellulose to make ethanol, thus the name *cellulosic ethanol* (Granda *et al.*, 2007). A group of researchers at the University of California at Berkeley has estimated that cellulosic ethanol has the remarkable potential of reducing the emission of greenhouse gasses by 90%, compared to conventional petroleum-based gasoline (Farrell and Plevin, 2006). Another analysis indicates that certain types of cellulosic ethanol are carbon negative, meaning that over the full process life cycle, more CO₂ can be removed from the atmosphere than the CO₂ being emitted into the air. Any technique that can reduce the carbon imprint is of course very environment-friendly and will help long-term sustainability.

Oil, sugar, and starch are first-generation *biofuels*, and it is easy to convert them to ethanol, diesel, or butanol thru conventional techniques. Cellulosic ethanol is a second-generation biofuel, produced from lingo-cellulosic biomasses. Conversion process of second generation biofuels is somewhat more complex. Third-generation biofuels, also known as drop-in fuels, are comparable to petroleum in composition and fuel value, and can be derived from different sustainable sources (cellulose, municipal waste, algae).

Two methods having higher potential for extraction of cellulosic ethanol are *cellulolysis* and *gasification*. Commercial-scale production of ethanol from cellulose has not been achieved yet, but it is considered to be the next generation of renewable energy because of its potential (IEA, 2006; Mabee *et al.*, 2004; US Department of Energy Biomass Program, 2013). There are four major sources of cellulose feedstock: wood residue from the wood industry, saw and paper mills, and furniture market; agricultural waste that comes from straw residues, corn stover, husks, and bagasse; dedicated energy crops, including herbaceous, woody crops, and tall grasses; and municipal solid wastes, which come in the form of paper and other cellulosic material (Nwakaire *et al.*, 2013).

Cellulolysis

The process of *cellulolysis* uses a biological approach. First, size reduction of the biomass takes place. This compaction increases efficiency of the conversion process, and makes it easy to handle. It may consist of grinding of agricultural products, or chipping of wood to achieve size uniformity. Next is the process of pre-treatment, during which the hemicellulose fraction from the biomass is broken down into simple sugars. Then comes the process of hydrolysis (also known as saccharification), where the remaining cellulose is hydrolyzed into glucose. During the next stage of fermentation, glucose is converted into ethanol. After fermentation of glucose and pentose, ethanol is separated from other components. The final step of dehydration is needed to remove residual water from the ethanol. Electricity required for ethanol production can be generated from lignin and other by-products, which are naturally produced during the biomass-to-ethanol conversion.

Gasification

Gasification is based on a thermochemical approach. Rather than breaking cellulose into sugar molecules, the process converts carbon in the raw material to a synthetic gas, using partial combustion. A particular kind of fermenter is then mixed with the produced CO₂, CO, and hydrogen. A microorganism other than bacteria is used for this fermentation. This microorganism ingests the produced gasses, forming ethanol and water. During the final phase of desalination, the produced ethanol is separated from water. New microorganisms are being tested for efficiency enhancement of the conversion process.

Various studies have been conducted for cost estimation of producing ethanol from cellulosic materials. Most of these cost estimates (Von Sivers and Zacchi, 1996; Lynd, 1996) are based on laboratory scale models. Capital cost assessment depends on factors such as raw material cost, cost of hydrolysis, and initial processing costs. This makes the total process cost highly dependent on local conditions and prices (Hahn-Hägerdal *et al.*, 2006).

The US congress enacted the renewable fuel standard in 2005 as a part of US energy policy, and amended it in 2007. Trying to reduce the dependence on fossil fuels, and to encourage the shift towards biofuels, a target was stipulated that by 2022 the volume of cellulosic biofuels should reach 16 billion gallons. This will be on top of 15 billion gallons of conventional corn-based ethanol (Kim and Kim, 2014).

Challenges and future prospects

Support for cellulosic ethanol and other advanced biofuels can be increased by mandating their use at state/provincial and country levels. Major challenges to make cellulosic ethanol widely available and viable are construction of commercial level plants, and various technical issues at the process level (Hahn-Hägerdal *et al.*, 2006). One issue is improving the process of enzymatic hydrolysis. This includes development of efficient enzymes, reduction in enzyme production cost, and devising novel technologies to handle high levels of biosolids. Another challenge is creation of more robust fermenting organisms. These advanced microbes should be more resistant to inhibitors, able to ferment all types of sugars in the raw material, able to work in tandem with concentrated hydrolysis, and should produce high ethanol concentration. One issue is the reduction in the number of process steps through higher levels of process integration.

Though cellulosic ethanol is a high-potential sustainable energy source with various advantages, there are some downsides as well. This fuel is more corrosive and it has the tendency of absorbing moisture from the atmosphere. Contamination can be an issue, making it difficult to ship the fuel through conventional pipelines. Automobile engines would need to be modified, as this biofuel is incompatible with majority of the components in existing auto engines.

Artificial Photosynthesis (AP)

Photosynthesis is a daily occurring natural process, through which plant leaves, green algae, and some other organisms (such as cyanobacteria) convert sunlight into chemical energy that can be later released and used as an energy source. The converted chemical energy is stored in the form of carbohydrates such as sugars, synthesized from carbon dioxide and water. The stored water and CO₂ are then converted into fuel and oxygen gas. This internal fuel is used by the organisms, and the oxygen gas is released into the atmosphere as a byproduct.

The name *artificial photosynthesis* clearly hints at an attempt to biomimic the unique natural photosynthesis process (De Vriend and Purchase, 2013; American Society for Microbiology, 2013). The target, obviously, is to store energy from sunlight in high-energy chemical bonds of a fuel (a solar fuel) (Crabtree *et al.*, 2004), and then decompose water into hydrogen and oxygen efficiently (Liu *et al.*, 2013). Hydrogen is a good energy carrier and can be easily converted to electrical power. This power generation process is environment-friendly, and does not give out harmful byproducts (Kim *et al.*, 2015). In a nutshell, artificial photosynthesis is the process of obtaining energy from sunlight and water. Photocatalytic water splitting separates out hydrogen and oxygen from water. Light-driven CO₂ reduction is another process being attempted to imitate the process of natural carbon fixation.

Research is ongoing in various related areas: design and construction of devices for direct production of solar fuels, photo-electrochemistry and its application in fuel cells, and the engineering of enzymes and photoautotrophic microorganisms for microbial biofuel and biohydrogen production from sunlight. Some of the unique components and devices used in the engineering of artificial photosynthesis and water splitting units include semiconductor particles, electrolyzers, artificial leaf (a solar water-splitting cell), dye-sensitized solar cells, etc (Esswein *et al.*, 2011; Lee *et al.*, 2013).

Challenges and future prospects

Artificial photosynthesis (AP) has a lot of promise as a sustainable energy source, with the possibility of efficiently producing solar fuels. Currently, the main hurdles are the catalytic steps needed for oxidation of water and production of fuels. It is anticipated that small-scale demonstration level systems will be launched within the next ten years (Cogdel *et al.*, 2010). The major driving force in AP research is rapid developments in the area of nanomaterials and nanotechnology, with possible contributions in light capturing, transportation of electrons, water splitting, and hydrogen storage (Nam, 2010). Metals such as hematite, cobalt, and manganese are competing in the production of inexpensive electrodes. Another research stream involves the production of methanol and increasing the capability of the AP system in using hydrogen generated from water splitting and atmospheric CO₂ to store in the form of formic acid (Hull, 2012).

As of now, some laboratory-scale prototypes have been made, using sunlight to split water and produce hydrogen. However, long-term stability has not been proven yet. Which process will come out as the most commercially viable one in terms of efficiency, durability, and cost, is yet to be seen. AP is a high-potential emerging renewable energy source, but this technology has its own drawbacks. There are various safety concerns related to hydrogen storage and transportation, especially because of the low energy density of hydrogen gas. Moreover, the materials used in the AP process get easily corroded in water and cause stability issues (Hull, 2012).

Conclusions

This article discusses the current status and future prospects related to the three interconnected and intertwined issues of renewability, recycling, and sustainability. The three topics are first defined and discussed, briefly touching upon their connectivity. The famous 3R drive of 'reduce, reuse, recycle' is then introduced, later adding 4R and 6R strategies. Renewable practices that can be sustainable are described. Renewable materials are explored, including cutting-edge ones such as rapidly renewable and biorenewable materials, and the more promising class of bioplastics. Renewable energies are described, the more prominent ones being biomass, biofuel, and biodiesel. Major threats to renewable resources are discussed, followed by sustainable recycling practices. In the end, current developments, associated problems, and future outlook of some emerging and state-of-the-art renewable technologies are presented. This includes marine or ocean energy, concentrated solar power and photovoltaics, enhanced geothermal energy, cellulosic ethanol, and artificial photosynthesis.

Introduction

Energy use is essential to all economic activities and to human well-being. Lack of access to reliable and affordable modern energy represents a constraint to economic and social development in many parts of the world. In the last three decades, the effects of energy consumption on economic growth have become a topic very significant both at the national and international level.

The energy-growth debate has been discussed extensively in the literature. Recent studies have disaggregated the energy data in order to examine, for instance, how electricity consumption is linked to economic growth. Understandably, the electricity-growth linkage merits attention, since most developing countries rely heavily on electricity. Nevertheless, the empirical findings have largely diverged. Thus, policy recommendations emanating from existing studies are often than not conflicting.

The relationship between energy consumption and economic growth has been an active research area. In paper (Alshehry and Belloumi, 2015) was investigated the dynamic causal relationships between energy consumption, energy price and economic activity in Saudi Arabia based on a demand side approach and results indicated that there exists at least a long-run relationship between energy consumption, energy price, carbon dioxide emissions, and economic growth. A better understanding of the relationship between economic growth, energy consumption, and CO₂ emissions is necessary according to study (Wang *et al.*, 2016). The results in Iyke (2015) were shown that there is a distinct causal flow from electricity consumption to economic growth: both in the short run and in the long run. Energy consumption played an important role in the increase of economic growth but with the consequence of high pollution (Saidi and Hammami, 2015). The influence of renewable energy consumption or its share to the total energy mix to economic growth is positive and statistically significant (Inglesi-Lotz, 2016). A strong relation between energy consumption and economic growth was found in study (Kantar *et al.*, 2016). In the long run, there exists also a bidirectional causality between renewable energy consumption and real gross domestic product (GDP) per capita, which argues that renewable energy is a crucial component for economic growth (Saidi and Mbarek, 2016). Results in investigation Nase (2015) of the causal linkage between the variables pointed that energy consumption (i.e., oil or nuclear) has either a predictive power for economic growth, or a feedback impact between with real GDP growth in all countries. Dynamic impacts of GDP growth, energy consumption and population growth on CO₂ emissions using econometric approaches for Malaysia was investigated in (Sohag *et al.*, 2015). The impact of energy consumption and the CO₂ emissions on economic growth using simultaneous-equation models with panel data for 58 countries over the period 1990–2012 was evaluated in Saidi and Hammami (2015) and the empirical results were shown that energy consumption has a positive impact on economic growth. A bidirectional time-varying causality between energy consumption and CO₂ emissions was shown in (Ajmi *et al.*, 2015; Pao and Tsai, 2011). To evaluate the dynamic behaviors of the energy consumption and CO₂ emissions, a few interdisciplinary studies have been conducted (Volker Krey *et al.*, 2012; Chen *et al.*, 2012; Fang *et al.*, 2015).

In this investigation adaptive neuro-fuzzy inference system (ANFIS) (Jang, 1993) was used to detect the influence of energy consumption from alternative, fossil and combustible renewables on the GDP growth rate prediction.

Methodology

Statistical Data and Study Area

One of the most examined issues in growth literature, recently, is the causal linkages between electricity consumption and economic growth. The modern day climate change, energy crises, rising prices of crude oil, and the ever-growing emission of carbon into the atmosphere have added momentum to the debate. The ability to establish the exact causal pattern between electricity consumption and economic growth is of immense relevance for policy formulation. In this study, we analyze the dynamic causal relationships between energy consumption and economic growth. Table 1 shows inputs and output parameters which were used in this study. The dataset was taken from World Bank database for European Union countries.

ANFIS Methodology

In the process of identification of variables in the ANFIS architectures, the hybrid learning algorithms were applied. The functional signals progress until the 4th layer whereby the hybrid learning algorithm passes. Further, the consequent variables are found by

Table 1 Input and output parameters

<i>Inputs</i>	<i>Parameters description</i>
Input 1	Alternative and nuclear energy (% of total energy use)
Input 2	Fossil fuel energy consumption (% of total)
Input 3	Combustible renewables and waste (% of total energy)
Output	Real GDP growth rate

Fig. 1 Parameters influence on GDP prediction for one input.

Fig. 2 Parameters influence on GDP prediction for two inputs.

Table 2 Correlation matrix of parameters influence on GDP prediction

	Input 1	Input 2	Input 3
Input 1	trn=3.8748, chk=3.9342	trn=3.7921, chk=3.8596	trn=3.8412, chk=3.9230
Input 2		trn=3.9907, chk=3.7853	trn=3.8968, chk=3.8011
Input 3			trn=3.9958, chk=3.7674

Fig. 3 ANFIS forecasted relationship between alternative and fossil energy consumption and GDP growth rate.

the least squares estimation. In the backward pass, the error rates circulate backwards and the premise variables are synchronized through the gradient decline order.

Results

ANFIS Results

Fig. 1 shows the input 1 (alternative and nuclear energy) has the highest influence on the GDP prediction. Fig. 2 shows the combination of the input 1 and input 2 forms the combination with the highest influence on the GDP prediction. Table 2 shows the correlation matrix of the numerical results for all single parameters and for the two inputs combination influence on the GDP prediction.

Fig. 3 shows the GDP growth rate changing in relation to alternative and fossil energy consumption.

Conclusion

There is a growing literature that examines the relationship between energy consumption and economic growth. The bulk of this literature focuses on developing, developed and emerging countries. It is important for policymakers to understand the relationship between energy consumption and economic growth in order to design effective energy and environmental policies. A general conclusion from these studies is that there is no consensus either on the existence of the relationship or the direction of causality between energy consumption and economic growth in the literature.

In response to growing concerns about energy consumption, numerous energy scenario or computable general equilibrium models have been developed worldwide to provide alerts, mitigation, adaptation, financial and sustainability policy options. However, rigorous evidence-based economic measurement and analysis of the trade-off between energy consumption and economic growth are still limited globally.

Therefore, this study aims at examining the relationship between energy consumption from alternative, fossil and combustible renewables and GDP growth rate prediction in European Union countries. In this study was proposed a new approach to overcome the forecasting difficulties of the growth rate prediction by removing some unnecessary input parameters. The main goal was to analyze the influence of different sectors of energy consumption on the GDP growth rate prediction. Results shown that the energy consumption from alternative and nuclear energy has the highest influence on the GDP growth rate prediction.

Reuse of Waste Corrugated With Coir Fibers as a Packaging Material

Mohd H Othman, Tun Hussein Onn University of Malaysia, Johor, Malaysia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Coir fiber is a coarse, short fiber naturally obtained from the tissues near the seed of the coconut palm (*Cocos nucifera*). This fiber is the most tough and thick of all natural fibers with low decomposition rate. According to Food and Agricultural Organization (FAO) of the United Nations, coir is one of the future fiber with lots of potential. For instance, this fiber could be used as packaging product such as paper. Typical paper is made of pulps derived from wood. Adding coir fiber with pulp, for example, pulps from waste corrugated, could be a good alternative. However, several mechanical tests should be performed, such as tensile and tear test, so that the mechanical properties of the new composition paper will be at par with current paper product. Certain analysis, such as the behavior of waste corrugated with coir fibers when it is beaten need to be carried out with different formulations. This new composition of paper should be recyclable, degradable and more environmental friendly. There are a number of researches that have been conducted with different composition, analysis, properties and formulation in utilizing coir as packaging material. For instance, [Gurav et al. \(2003\)](#) had studied the mechanical properties of paper-pulp packaging and [Gabriel et al. \(2007\)](#) had removed the ammonia from coir fiber by utilizing gas phase bio-filter and categorized the performance of coir fiber as packaging material. [Monteiro et al. \(2008\)](#) used coir fiber/polyester composites to assess the structural characteristics and mechanical properties, while [Beg and Pickering \(2008\)](#) had utilized beating process to discover their effects towards kraft fiber reinforced polypropylene composites. As an additional information, coir fiber also could be a good sound barrier, as mentioned by [Zulkifli et al. \(2008\)](#) and [Mohd Nor et al. \(2010\)](#). As a wrapped up, a review made by [Sanjay et al. \(2018\)](#) had listed coir as one of potential fibers to be applied for natural fiber-reinforced polymer composites.

Procedure of Paper Making by Using Waste Corrugated/Coir Fiber

Firstly, the waste corrugated and coir fibers need to be cut in small pieces, ranging from 20 to 50 mm. For a weight of 25 grams, 15% of waste corrugated and 85% of coir mixture were prepared for a trial. To produce a mixed pulp, this composition need to be blended for 5 min. Then the mixture was transferred into a container. A deck need to be immersed in this container and then raised up slowly. The screen was shaken for a few minutes to ensure the water had been drained back into the container. After that the screen was flipped on the cotton cloth with a sponge used to squeeze off the water. Slowly the screen was pulled off and finally the sheet of paper was completely prepared. The prepared mixture was dried within the environment temperature for 8 h, and then pressed using a padding machine with 3 kg/cm² of pressure to make sure that all papers have the equivalent thickness.

Mechanical Treatment and Properties of Paper

According to [Casey \(1952\)](#), to make a paper the cellulose fibers need to be treated mechanically. The treatment, such as bruising, rubbing, crushing, refining and beating are essential in the paper making process. Beating time process is the most important treatment, because it will increase the density and strength of the fibers. Therefore, mechanical test such as bursting strength, tensile strength and folding endurance will produce good results. There was a drawback such as decreasing tearing resistance but it will increase smoothness, hardness and amount of bonding fibers.

Common mechanical properties of papers generally measured through tensile and tear strength. Based on [Peperonweb.com](#), tensile and tear relationship was inversely proportional to each other. A paper formed at maximum tear value will be low in tensile strength and the paper with a maximum tensile strength, will be low in tear. The flow of mechanical test was displayed in [Fig. 1](#).

The objective of tensile and tear test towards corrugated waste/coir fibers were to obtain a quality paper with the maximum percentage of coir and minimum beating time. As mentioned before, the mixture of 85% of coir fibers and 15% of corrugated waste was used as a trial. As a pre assumption, higher percentage of coir fiber will produce more lignin, which could weaken the paper's structure. Hence, the increased percentage of waste corrugated could improve the structure of the paper. So it is important to find the optimum formulation. [Table 1](#) shows the result for mechanical test by using 85% of coir fibers as the main raw material. With referred to [Table 1](#), the maximum load that the 85% of coir fibers/15% waste corrugated paper could withstand was 163.47 N for tensile load. As for tear test, the maximum number was 26.95 N. As for extension results, the value of tensile and tear test are 1.95 mm and 1.87 mm respectively. Based on these values, it can be summarized that at the composition is performing their duty as a good paper, and the development of these mixtures as a packaging material product have a potential to be explored.

[Table 2](#) shows the physical properties measurement of sample with 85% of coir fibers/15% waste. The thickness of samples depends on time for pulps were beaten. Then, the weight and area of the sample were measured. After that, the grammage of the sample was calculated, which was approximately between 177 and 178 g/m². These values were significant by comparing with the paperboard's grammage, which is between 120 g/m² to 300 g/m², with +/− 5% of trade tolerance. Hence, this waste corrugated coir fiber can be considered as paperboard.

Fig. 1 The flow of mechanical test for paper.

Table 1 The mechanical experiment results for 85% of coir fibers/15% waste corrugated

Test number	Results
Maximum load on tensile test (N)	163.47
Maximum load on tear test (N)	26.95
Extension of tensile test (mm)	1.95
Extension of tear test (mm)	1.87

Table 3 The preliminary experiment observation

Mixture percentage	Observation
25% coir fibers and 65% waste corrugated	Smooth surface. Nearly same as a normal paper. Gray in color. Easy to beat and blended. Run lightly and noise produced was normal.
45% coir fibers and 55% waste corrugated	Gross surface. Physical color was balance between gray and brown. Hard to beat the raw materials and make noise.
65% coir fibers and 35% waste corrugated.	Rough surface. Brown in color. Hard to blended. Run heavily and lot of noise.

Note: Othman, M.H., Main, N.M., Mon, S.Z.K., Mohamad, Z., 2013. Development of paper using coir fibers as a packaging product. Asian Journal of Scientific Research 6 (2), 207–216.

Table 3 shows the general physical observation when the process of beating was done for another composition of fibers to develop the papers, which were 25% fibers + 65% waste corrugated, 45% coir fibers + 55% waste corrugated and 65% coir fibers + 35% waste corrugated. These samples were prepared to cross-machine direction fiber orientation. Based on the observation, if more coir fiber added in the composition, the paper surface will become rougher and less smooth. Difficulties happened when heavy beating process involved (hard to blend) and causing lots of noise during the process. Papers with more corrugated waste were better in the sense of smooth surface and easy processing.

Fig. 2 shows the orientation of fibers and colors based on coir fiber/waste corrugated percentage. As for 25% of coir fiber samples, the color was gray. When the coir fiber increased to 45%, the color balanced up between gray and brown. At 65% of coir percentage, the color of paper produced was brown. Based on Food and Agricultural Organization (FAO), if the coir was cured in a

Fig. 2 Orientation of fibers and colors based on coir fiber/waste corrugated percentage. Reproduced from Othman, M.H., Main, N.M., Mon, S.Z. K., Mohamad, Z., 2013. Development of paper using coir fibers as a packaging product. *Asian Journal of Scientific Research* 6 (2), 207–216.

brine a longer period of time, the fiber's color will become whiter. Better fiber color and orientation could be produced by using technology such as coconut husk defibering machines. White coir could be manufactured into ropes or fishing nets. However, more robust product could be made from brown coir such as doormat, rugs, and panels for insulation

The most significant findings was the composition of raw materials could be utilized according to their function and economical factor. For example, higher quality of paper could use the treatment for 25% of coir mixed with 75% of waste corrugated with 20 min of beating time. This combination was selected for easier manufacturing process, with desired tensile strength and tear strength. As for the further research, some reference might be useful to mark coir/wasted corrugated paper as a commercially viable, not petroleum dependent and sustainable solution packaging product in future. For instance, other techniques to analyze the findings by Fällström *et al.* (2000). They have established some results that indicated the bending waves were influenced by mechanical properties such as density, thickness, bending stiffness, anisotropy and also by tensile forces in the paper.

Background

Modification of asphalt binder is not a new concept and has been widely employed to enhance the performance of asphalt mixture, and decrease the problems that are associated with bitumen (Airey, 2002). The mechanical properties of modified asphalt are dependent on the polymer content and the type of polymer used (Ghorbel *et al.*, 2008; Isikyakar and Sengoz, 2008; Lu and Isacsson, 1997). With the addition of polymers, many properties can be improved across the entire temperature spectrum (Kalantar *et al.*, 2012a). Two types of polymers are typically used in the modification of asphalt, namely elastomer and plastomer (Aksoy *et al.*, 2012).

Electronic waste (e-waste) incorporates electronic equipment and products consisting of discarded personal computers, monitors, hard drives, copiers, facsimile machines, cellular phones, and televisions. Processing e-waste materials yields valuable raw materials, but this value is offset by the fact that e-waste generally contains hazardous materials (Khan *et al.*, 2007). E-waste contains potentially hazardous materials along with valuable recyclables (Nagurney and Toyasaki, 2005). E-waste also poses additional recycling challenges, namely its slow decomposition rate and its relatively short life span due to changing or upgraded technology demands. Electronic waste plastics compose approximately 23.3% of the mass of disposed computers (Robinson, 2009). The biodegradation process of e-waste materials can last from 450 years to an indefinite period of time for materials such as glass (Santos *et al.*, 2010). Within the United States, there was an estimated 1.5 billion lbs. of e-waste generated, as of 2006, with only 10% of that amount was actually recycled (Khan *et al.*, 2007). Projections of e-waste estimate that 3 billion tons of consumer electronics will eventually end up as e-waste in the United States (Dawson and Landry, 2004). Fig. 1 shows several stages for the successful implementation of e-waste plastics within bituminous materials.

A driving force behind the concern for the disposal of e-waste is the rapid growth of computer technology and the subsequent amount of obsolete computer technology; it's projected that nearly 1 billion computers are obsolete (Ladou and Lovegrove, 2008). Legislation has been introduced to limit the quantity of e-waste placed within state and local landfill sites due to the potential environmental impact which e-waste could pose to the environment (Dawson and Landry, 2004). Specifically, national and international laws are now only addressing the need to significantly limit and reduce e-waste flowing into limited landfill space (Nagurney and Toyasaki, 2005). New research efforts with various potential applications should be developed and address environmental hazards which e-wastes may pose to society; due to the increasing worldwide production e-waste, and the subsequent legislation limiting the location and quantity of e-waste.

The quantity of e-waste plastics is becoming problematic for the waste management and plastics industry. The sheer amount of e-waste plastics has made disposal difficult and increased the urgency for profitable applications for waste electronic plastics. It is imperative to identify applications where e-waste plastics can be used in a sustainable manner. This paper is intended to be used as an initial effort to identify applications of e-waste plastics within the asphalt industry and highlight its benefits. Potential pitfalls which practitioners and researchers may encounter when using e-waste plastics are also discussed.

Asphalt Modifications

Bitumen has been used for many years as a road paving material as well as other uses. Temperature sensitivity of asphalt binder causes the most frequent deteriorations of road pavement such as rutting, fatigue cracking, and thermal cracking (Kebritchi *et al.*, 2011; García-Morales *et al.*, 2006; Ig, 1999). In asphalt mixture, bitumen acts as an adhesive, which bonds the aggregates together. Loss of bonding influences the performance, it is not only affects the resistance to moisture damage of asphalt mixture, but also the issue of poor temperature susceptibility (Zhang *et al.*, 2012). Asphalt mixture strength is attributed by the cohesive resistance of an asphalt binder, adhesive bond between binder, aggregates, and aggregate interlock as well as frictional resistance between aggregates (Curtis, 1990). At the same time, quality aggregates, and binder bonding are also important aspects to consider as the

Fig. 1 Applications of e-waste as novel additive in asphalt pavement.

aggregates protects the whole pavement against shear and compression stresses. It also helps to reduce the effect of UV radiation (Estevez, 2009; Dawson *et al.*, 2008; Berdahl *et al.*, 2008; Palmer, 2005). The aggregates connections mainly depend on the cohesive force produced by the binder.

Even though various types of polymers have been used to enhance the performance of asphalt composite, only a few of them are considered as satisfactory based on the performance and economic standpoints (Pinnavaia and Beall, 2000; Jahromi and Khodaii, 2009). You *et al.* (2011) stressed that these challenges became motivation to scientists to reduce the temperature susceptibility at a wide range of temperatures, at the same time maintaining the workability at construction temperatures through asphalt modification.

Applications of Polymer in Asphalt Modification

Various types of polymers have been used to chemically or mechanically improve the properties of asphalt binders, which can be classified into three different categories, elastomer, plastomer and reactive polymers (Brown *et al.*, 2009a; Polacco *et al.*, 2006; Kalantar *et al.*, 2012b). There are different types of rubber (elastomer) materials have been used as asphalt modifiers, such as styrene-butadiene-styrene (SBS) (Alam and Hossain, 2017; Hao *et al.*, 2017), natural rubber (Wen *et al.*, 2017; Al-Mansob *et al.*, 2017), styrene-isoprene-styrene (SIS) (Zhu *et al.*, 2014), polychloroprene latexes as well as grounded waste tires (crumb rubber) (Yang *et al.*, 2017; Zhang *et al.*, 2017; Shirini and Imaninasab, 2016). Meanwhile, the polymers that can be classified as plastic (plastomer) modifiers are polyethylene (Yan *et al.*, 2015), polypropylene (Nekhoroshev *et al.*, 2017), ethyl vinyl acetate (EVA) (Brovelli *et al.*, 2015), poly-vinyl chloride (PVC) (Maharaj and Maharaj, 2015), ethylene propylene (EPDM) (Rahi *et al.*, 2015), epoxy resin (Luo *et al.*, 2017), and poly olefins (Wei *et al.*, 2014). It was found that the rubber modifier is implemented to resist deformation and quick recovery when stress is removed. In contrast, the plastic modifier is exhibited differently by having the asphalt mixture with quick early strength but may fracture under strain (Brown *et al.*, 2009a). According to Polacco *et al.* (2006) the reactive polymers consist of functional group, such as ossiranic ring or succinic anhydride that are capable in forming chemical bonds with asphalt molecules that can be supported by adding on sulfur or mineral acids compound. Table 1 presents some of the major polymers that have been used in studies of polymer modified asphalt.

Elastomers, plastomers, and combinations of the two have properties that can help to remedy different types of asphalt pavement deterioration, such as rutting, moisture damage, as well as fatigue and thermal cracking. Polymer modified asphalt should be produced with a polymer and asphalt that are compatible (Polacco *et al.*, 2005; Jin *et al.*, 2002; Zhang *et al.*, 2009; Polacco *et al.*, 2006). In general, asphalt binders that modified with polymers that have a low compatibility can perform poorly in storage. Additionally, phase separation also might occur, leaving an inhomogeneous material while storing the

modified binders at high temperatures (Kalantar *et al.*, 2012a; Fang *et al.*, 2009; González *et al.*, 2004; Navarro *et al.*, 2009; Polacco *et al.*, 2005; Jin *et al.*, 2002).

The polymer should be homogeneously dispersed into asphalt to ensure proper adhesion of the asphalt binder. However, incompatibility between the binder and the polymer is sometimes inevitable. As a result, it is difficult to establish and bond, either in terms of a physical or chemical manner (Estevez, 2009; Marzocchi *et al.*, 1981). Prior to gaining a better performance, an application of coupling agent in organic materials or treating inorganic fillers has been used. This enhances the materials cross-linking by means of winding up covalent bonds or molecule chains, thus improving the performance of composites (Hristov and Vlachopoulos, 2007; Liang *et al.*, 2012). It was found that a small amount of coupling agent could increase shear resistance in mechanical properties (Hristov and Vlachopoulos, 2007). There are various types of coupling agents that have been used to improve the bonding of composite materials such as: silane, zirconate, dicarboxylic anhydride, titanates and phosphate ester. However, the most important commercial coupling agents are formed by silane and titanate (Martí-Ferrer *et al.*, 2006).

Application of Plastomers in Asphalt Modification

Plastomer is a type of polymer that typically uses to help remedy problems related to deformation by forming a rigid network to resist distortion (Airey, 2002; Polacco *et al.*, 2005, 2006). In polymer modified asphalt typically the plastomers that are used include polyethylene (PE), polypropylene (PP), ethylene vinyl acetate (EVA), polystyrene (PS), and high impact polystyrene (HIPS). Each form of plastomers has its own level of compatibility with binder, and therefore changes the properties of the binder differently.

Polyethylene (PE) is a plastomer that has a wide range of properties depending on its structure (Polyethylene, 2008). Fang *et al.* (2012) investigated the modification of asphalt with the use of a combination of PE packaging waste and organophilic montmorillonite (MMT), which led to a decrease in penetration and an increase in softening point and ductility. Hence, results in a better resistance to permanent deformation, low temperature cracking, and stability at high temperature. Polacco *et al.* (2005) studied the use of PE based polymers as modifiers for asphalt. It was found that in all cases the PE based polymers did not form a homogeneous structure, however it was found to be stable during storage. Based on a study carried out by Punith *et al.* (2011a) additions of PE has result in a higher asphalt binder viscosity, less susceptibility to damage due to moisture, and an improvement in stripping characteristics. Moreover, Fang *et al.* (2008a) used waste PE as an asphalt modifier, which resulted in an increase in the softening point and ductility.

Polypropylene (PP) has superior performance in stiffness and strength (Khattak *et al.*, 2012). Al-Hadidy and Yi-qiu (2009a) studied the benefits of using polypropylene as a modifier to asphalt. In general, the PP was dissolved completely in the asphalt cement. The addition of PP has resulted in lower penetration, which leads to an improvement in shear resistance and a reduction in temperature susceptibility. A higher PP content indicated a superior resistance of asphalt mixtures to deformation. Giavarini *et al.* (1996) investigated the use of stable polypropylene to modify asphalt. When a poly phosphoric acid treatment was applied there was an increase in softening point and penetration index.

Ethylene-vinyl acetate (EVA) is composed of ethylene and vinyl acetate, which helps to resist deformation with its rigid three-dimensional networks (Brown *et al.*, 2009b). It is used to improve the properties of asphalt binder for pavement applications.

Airey (2002) studied the morphology, thermal properties, and fundamental rheological properties of EVA modified bitumen through a series of test and found that with the addition of EVA to asphalt, there is an improvement in temperature susceptibility and its stiffness. Ghorbel *et al.* (2008) specified that additions of EVA to bitumen have significantly improved the resistance to permanent deformation, softening point and stiffness, with a decrease in the Fraass breaking point and penetration value. González *et al.* (2004) investigated the mixture stability and viscoelastic response of recycled and virgin EVA modified bitumen. The outcome of the study indicated that the addition of EVA has remarkably improved both resistance to thermal cracking and rutting. Zorn *et al.* (2011) also concluded that EVA modified bitumen has improved both behaviors.

Polystyrene (PS) is made up of the monomer styrene that is in solid state at room temperature and will turn to a liquid and eventually will foam when heated (Polystyrene Properties, 2010). PS is ridged and has limited flexibility (Polystyrene Properties, 2010). High impact polystyrene (HIPS) is a tougher version of polystyrene. Jin *et al.* (2002) found that the PS modified asphalt does not store well at high temperatures. The properties of PS modified asphalt can be improved in the presence of sulfur and SBS. At a higher content of PS the softening point is increased, yet resulted in a decrease in penetration. Fang *et al.* (2008c) indicated that a higher ductility can be achieved when using PS as an asphalt modifier. Meanwhile, Colbert and You (2012a) specified that the low temperature performance was improved the most when 5% HIPS (electronic waste composed of HIPS) was added to the binder.

Bulk E-Waste Plastic Considerations for Bituminous Material Modification

When designing long lasting roadways, the pavement engineer should consider the type of e-waste plastic and its behavior, alongside with the design of asphalt pavements and the grade of binder accordingly. Typical e-waste plastics available include ABS and HIPs (Mohd Hasan *et al.*, 2016), PP, PS, styrene acrylonitrile (SAN) (Ali *et al.*, 2015), PE (Wang *et al.*, 2014), polyurethane (PU) (Carrera *et al.*, 2015), polyamide (PA) (Lei and Cao, 2015), acrylonitrile butadiene styrene-polycarbonate (ABS-PC), and polyphenylene oxide (HIPS/PPO) (Santos *et al.*, 2010).

ABS is a heterogeneous multiple phase polymer with a rubber component and a combination of styrene acrylonitrile (Khan *et al.*, 2007). ABS has good impact strength, chemical resistance, and toughness, and rigidity (Achilias *et al.*, 2009). ABS-PC is shown to have good tensile, impact, and strength properties especially during grinding and injecting molding although there are variable ranges of melt flow indices, and poor performances for ultraviolet (UV) susceptibility impact strength, and viscosity for ABS-PC plastics (Dawson and Landry, 2004). Polycarbonate is a common thermoplastic used and has excellent physical and chemical properties, transparency, a high tolerance for heat distortion, high impact properties, and thermally stable (Achilias *et al.*, 2009).

PE and PE-based copolymers have been used to modify the performance of asphalt binder and mixture over many years (Fang *et al.*, 2008c; Polacco *et al.*, 2005; Stastna *et al.*, 2003; Habib *et al.*, 2011; Fang *et al.*, 2008b; Yousefi, 2004). The PE and PP are categorized as elastomers which can bring a high rigidity to the material and improved the resistance to permanent deformation under traffic loads (Polacco *et al.*, 2005; Stastna *et al.*, 2003).

Within the e-waste recycling stream, 33% of the waste stream consists of plastics with 16% composed of computer equipment (Dillon, 1999). The percentages of e-waste plastic resins consist of the following: 31% PS, 16% ABS, and 13% PP (Dillon, 1999). When considering household, e-waste plastics consist of 35% with 3% of the total household waste stream coming from personal computers (Kang and Schoenung, 2004). Typical personal computer plastic waste values consider the amount of impurities within the plastic and type of personal computer component. For instance personal computer circuit boards must have no more than 3% impurities, recycled personal computer plastics must have no more than 4% impurities, hard mix plastic must have no more than 6% impurities (Das and Matthew, 1999). Plastics from external product casings are 20% of the material mass and a valuable end of life recyclable product (Masanet and Horvath, 2007). Numerous researches have been conducted to investigate the applicability of various e-waste plastics. Balart *et al.* (2005) characterized ABS and PC waste plastic properties showing a decrease in mechanical properties versus virgin plastics but favorable to various engineering plastics. Liu *et al.* (2011) conducted an investigation to determine if e-waste plastics particle size affects the bulk properties of the composite material and if there are any agents available which would improve compatibility between the powder and composite matrix. Liang and Gupta (2000a,b, 2001) characterized the properties of typical e-waste plastics for use in recycling applications. Finally Mural *et al.* (2011) characterized polypropylene and waste HIPS blends for use for various packaging applications.

Waste Plastic and E-Waste Plastic Applications for Asphalt Concrete Research

The utilization of waste material in HMA mixtures is a promising way to efficiently use e-waste plastics, but pavement engineers must consider many factors in order to successfully implement these e-waste materials within HMA. Pavement engineers should not sacrifice pavement performance, cost, or contribute to a larger disposal problem (Li *et al.*, 2010). Despite many factors to consider in deciding whether e-waste plastics are appropriate for a given pavement project, the use of waste additives within asphalt concrete mixtures have been shown to bring contractors savings in roadway repair and reconstruction operations. HMA has successfully lined reservoirs within the United States, and chemically restrict waste materials within HMA (Li *et al.*, 2010). Researchers who have been successful in implementing waste plastics within asphalt binder and mixtures include Schroeder (1994). The use of low density polyethylene (LDPE) from waste plastic and sandwich bags were assessed. The LDPE was converted to pellets and mixed into the asphalt binder at a range 4%–7% by weight of asphalt binder (Schroeder, 1994). Hinişliolu and Ağar

conducted an investigation for high density polyethylene (HDPE) to determine if it was possible to successfully integrate HDPE as a polymer modified asphalt concrete mixture. Their results indicated that 4% HDPE modified asphalt mixture had a higher Marshall stability versus virgin mixtures, which presented a higher mixture stiffness and ability to distribute pavement loading (Hinisliolu and Aar, 2004). The long term aging effect of polypropylene modified HMA was investigated by Othman (2010). Whereas, the PP powder was blended into asphalt mixture, and specimens were going through aging process to simulate pavement condition in the field between 5 and 10 years after the placement. The modified mixture was shown to contribute to surface roughness and offset of the hardening effect of aged asphalt concrete mixtures (Othman, 2010).

Agilan (1993) conducted a study using various polymer additives to improve the performance of asphalt mixtures. All tested polymer modified asphalt mixtures has higher mixture stiffness and strength. Whereas the mixture prepared using Kraton has the highest flexibility and strength compared to Elvax and Novophalt modifiers (Agilan, 1993). Jeong *et al.* (2010) conducted a laboratory investigation of waste polyethylene (WPE) film for asphalt pavement mixtures using Marshall Stability test. The result indicated that asphalt mixture modified with 12% WPE provided the best performance compared to the control and polymer modified HMA mixtures. Meanwhile, Morrison *et al.* (1994) who investigated the performance of asphalt mixtures modified using combination of waste plastics and scrap tires (rubber powder), concluded that the combination help improved the high temperature performance in terms of loss moduli, loss tangent, and complex modulus (Morrison *et al.*, 1994). Punith and Veeraragavan (2003, 2010) and Punith *et al.* (2011b) incorporated the LDPE plastic bags for the preparation of asphalt mixtures. Based on the result, it has considerably improved the resistance to fatigue cracking and rutting potential of asphalt mixtures.

Colbert *et al.* (2011) investigated the low temperature performance of asphalt binder at various percentages of e-waste plastics. The preliminary results showed that e-waste modified asphalt binders can meet the low temperature performance criteria of virgin binder. Despite the investigation showing that the e-waste modified binder was stiffer at low temperatures compared to virgin asphalt binders. Lower percentages of e-waste plastics were implied to provide adequate low temperature performance compared to unmodified virgin asphalt binders.

Several research have been conducted (Achilias *et al.*, 2009; Jeong *et al.*, 2010; Anandhan *et al.*, 2002; Li *et al.*, 2007; Yokoyama and Iji, 1995) to improve the impact properties of ABS. Methyl methacrylate butadiene styrene was added to enhance the impact resistance of ABS (Anandhan *et al.*, 2002). Jeong *et al.* presented an attempt to assess the performance of different percentages of WPE film in asphalt mixtures using the Marshall mix design (Jeong *et al.*, 2010). An investigation by Yokoyama and Iji (1995) investigated the use of printed wire boards from electronic materials as filler for resin construction materials. This investigation pulverized printed wire boards into an effective size of 150 μm , and tested versus talc, calcium carbonate and silica powders. Despite the difficulty in pulverizing and re-melting the printed wire boards, it was shown that the printed wire board powder improved mechanical strength and thermal expansion properties versus the talc, calcium carbonate, and silica epoxy resin blends. Finally, it was concluded that it was feasible that printed wire board powder could be used effectively as a construction filler by separating the powder into copper and nonmetallic fiberglass (Yokoyama and Iji, 1995). Using an industrial shredder and a mechanical grinder the authors were able to reduce the size of bulk e-waste plastics into chips and powders (Colbert and You, 2012b). Other research efforts to improve the properties of e-waste plastics was performed by Achilias *et al.* (2009) The research was focused on recycling ABS, PC, and PS through polymer-chemical structure identification and verification using Fourier Transform Infrared Spectroscopy (FTIR) and Differential Scanning Calorimetry (DSC).

Recycled E-Waste Thermoplastic Processing Efforts for Asphalt Pavement Use

Most e-waste plastic recycling efforts focus on high priced plastics such as PC and ABS-PC due to the compounds covering sourcing and processing costs along with competitively pricing the product for resale (Dillon, 1999). Recycling e-waste consists of three steps: (1) recovery of retired electronic devices typically three to five years or longer, (2) pretreatment of e-waste where paints are removed, plastics are reduced in size, washed, sorted, filtered, and dried, then, (3) e-waste components are sorted through froth filtration, density, and or electrostatic means (Flaris *et al.*, 2009).

Obstacles to successful recycling of various e-waste plastics include; enforcement and reliability of the state and national regulations, few specified orders for recycled materials, lack of market forces driving the use of recycled plastics, and perception that recycled plastics are weaker than virgin plastics (Dillon, 1999). The expected cost saving of using processing and recycled resins range from 10% to 30% savings compared to virgin materials (Dillon, 1999). Recycled plastics provide the most salvage value for e-wastes other than metals. Typically, the percentage of plastic in e-waste products range from 15% to 30% (Achilias *et al.*, 2009). E-waste plastics are usually thermoplastics which can be re-melted to make new products that are preferred over thermosetting resins (Kang and Schoenung, 2004). Due to industrial technology advances, the demand to successfully recycle thermoplastics was greatly influenced by the economic, institutional, and political pressures (Dillon, 1999).

In terms of energy consumption, ABS-PC recycling saves roughly 100 MJ of primary energy and 5 kg CO₂ emission per enclosure versus dumping the ABS-PC waste within a landfill (Masanet and Horvath, 2007). One strategy proposed in Khan *et al.* (2007) was to incorporate e-waste plastics into high value products, and use correct quantity of recycled plastic with virgin plastics. For instance, recovery of copper and printer board plastics through pulverization can be performed for a value application. Copper waste printed wire boards were pulverized, and separations of copper, fiberglass, and resin has produced approximately 94% recovery rate for copper, as well as metallic and nonmetallic powder with 100–300 μm in size (Yokoyama and Iji, 1995). Processing techniques used for this investigation included corona separation, grinding, rolling, milling, and pulverizing to reduce

the particle size of the waste circuit board (Yokoyama and Iji, 1995). Recently, Miloudi *et al.* (2011) developed a method to separate and sort granular e-waste plastics such as HIPS, ABS, and PC using electrostatic separation with a propeller driven turbo-charging machine. Dawson and Landry reported a success in recycling HIPS, and ABS-PC that contain several types of flame retardants (Dawson and Landry, 2004). Xia *et al.* (2012) also investigated e-waste modified binders using grounded e-waste plastic polymers and potassium per sulfate as a free radical initiator. The team optimized asphalt binder performance for softening point and ductility using 6% e-waste plastic polymer by weight.

Mohd Hasan *et al.* (2016) conducted a study to evaluate the performance of e-waste modified asphalt binders. E-waste modifiers ABS, ABS-PC and HIPS with 100% of materials passing through 300 μm sieve were studied. The e-waste modifiers were blended with the control binder under two different conditions namely untreated and chemically treated. The chemically treated modifier was processed with cumene hydrogen peroxide before blending into the bitumen to reinforce the molecular bonding between e-waste plastics and asphalt binder. Based on the outcome of the study, the treatment with the initiator has significantly increased the stiffness of the e-waste modified asphalt binders, which attributed to a better integrity between materials and improved the resistance to rutting. In the study, free radical initiator was introduced to enhance the performance of e-waste modified asphalt binders. Free radical initiator was expected to promote covalent bonding between the additive and the binder to promote interfacial adhesion as presented in Fig. 2, and between different parts of the asphalt itself to enhance branching (Fig. 3). Fig. 4 shows the reaction by radical initiator can forms reactive radicals. The new radical ($\text{RO}\bullet$) can abstract an $\text{H}\bullet$, leading to a reactive radical on a polymer backbone on hydrocarbon components that are commonly present in bituminous asphalt leading to new reactive radicals. The coupling of radicals forms an activated styrenic radical from e-waste and a radical on an activated aromatic component of asphalt.

E-Waste Recycling Challenges for Successful Asphalt Pavement Applications

End of life for electronic equipment is the point when electronic product is past its usable life and disposed to landfills (Santos *et al.*, 2010). It was estimated that roughly 48 million personal computers were scrapped in the year 2000 (Anandhan *et al.*, 2002). The amount of e-waste is likely to increase due to rapid innovations in technology and more efficient production systems. Therefore waste management applications and strategies must be developed to meet the goal to lift the burden of disposing solid waste created by the scrapping of e-waste materials (Ismail and AL-Hashmi, 2008). A waste management strategy proposed by Reimer and Sodhi (2001) and Reimer *et al.* (2000) is an electronic recycling network to optimize the network for collecting, processing, and integrating e-waste recycling partners. The utilization of demanufacturing plants is crucial to effectively reduce the amount of e-waste now and in the future.

The main concern on the applicability of waste materials in general is the presence of various hazardous materials contained within e-waste products. Among the major concerns are heavy metals such as cadmium (Cd), chromium (Cr), mercury (Hg), lead (Pb), and antimony (Sb) and brominated flame retardants (Santos *et al.*, 2010; Shenoy and Patil, 2010; Li *et al.*, 2007). The potential pollution effects of unmitigated e-waste dumping is the landfill leaching of toxins to water sources, air pollution of toxins from burning e-waste, and the potential exposure hazards that may occur from the manual dismantling of e-waste, along with long periods of biodegrading from e-waste and plastic bags (Li *et al.*, 2007; Ismail and AL-Hashmi, 2008). Several efforts have been taken to address and quantify the amount of hazardous materials present in plastic e-waste components. Dawson and Landry (2004) conducted a toxicological and environmental assessment for flame retardants containing ethane 1,2 bis(pentabromo-

Fig. 2 Free radical initiators decompose to produce alkoxy ($\text{RO}\bullet$) and/or hydroxy ($\text{HO}\bullet$) radicals which can then induce chemical reactions that were expected to promote covalent bonding between the additive and binder to promote interfacial adhesion. phenyl) (EBP) and ethylene 1,2 bis(tetrabromophthalimide) (EBTBP) within HIPS. It was shown that there was little environmental or health risk for its use under European Union e-waste regulations (Directive, 2003).

Musson *et al.* used a toxicity characteristic leaching procedure (TCLP) analysis to test e-waste devices for lead leachate and determined that all electronic devices tested failed at least one TCLP test and had lead above the toxicity characteristic (TC) limit in the majority of tests; although the rate of failure was more prevalent for cell phones and remote controls than the personal computers, Central Processing Units (CPUs) and printers (Dawson and Landry, 2004; Musson *et al.*, 2006). Robinson (2009) also reviewed the use of the TCLP analysis for evaluate the heavy metal leaching susceptibility in landfills; the review found that e-waste disposal in modern landfills were not likely to lead significant amounts of plumbum, but the chemical slurry leached from e-waste would likely harm aquatic organisms (Robinson, 2009). Santos *et al.* (2010) also conducted a study quantifying toxic elements within e-waste plastics through slurry sampling by electro thermal atomic absorption spectrometry. Samples tested by Santos *et al.* (2010) originated from cellular phone and personal computer plastics such as PC and ABS blends fully or partially dissolved in dimethylformamide (DMF). Based on outcomes of the study, only ten samples were within values for the European Council (EC) directives for cadmium. Lead and chromium had values in agreement with the EC directives (Directive, 2003).

A study conducted by Colbert and You (2012b) specified that, the pumping difficulty based on viscosity at 135°C is expected to increase when modifying asphalt binder with e-waste plastic powders. But, the viscosity results for the e-waste modified binders have met the Superpave specification. Authors also found that the e-waste modified asphalt binders which can meet the low temperature performance specifications at minimum amount of e-waste plastic. In general, e-waste modified asphalt binders are stiffer compared to virgin asphalt binders. Additionally, it tend to have a greater compaction and mixing temperature versus neat asphalt binders, Incorporations of a higher percentage of e-waste plastic has resulted in a higher compaction temperature as well as raised its viscosity and complex moduli (Colbert and You, 2012b).

Government legislation and the growing numbers of obsolete personal computers has led to the rapid increase in de-manufacturing plants for e-waste (Das and Matthew, 1999). As material purity increases, recycling costs generally decrease, therefore disassembly procedures must be designed to increase purity of recyclables (Das and Matthew, 1999). A major limitation for many recyclables is the amount of impurities for each recycling process can tolerate that directly affects the market price and quality of material. An example of a valuable plastic e-waste recyclable are personal computer enclosures, which disables easily and contains valuable resins making it a likely recycle source (Masanet and Horvath, 2007). A typical personal computer demanufacturing plant has 10–15 employees which process 10 million lbs. within a 5000 m² on a 2000 h/year schedule (Masanet and Horvath, 2007). Although the majority of plastic from e-wastes are recovered in an electronic demanufacturing plant, the various additives within

some plastics prevent the recycled plastic from reentering the original recycle stream and must be used for other applications or burned for fuel (Das and Matthew, 1999). Generally, the percentage of e-waste material which arrives at the recycling plant, and not recycled ranges from 10% to 40% (Das and Matthew, 1999). Demanufacturing of plastic e-waste may include processes such as gravity separation and electrostatic separation (Yokoyama and Iji, 1995). The steps within the demanufacturing process involves three phases: the first phase is to improve accessibility to the various metallic and nonmetallic electronic product parts, the second phase recovers any valuable parts and sub-assemblies, meanwhile the third phase of disassembly further separates e-waste parts for reprocessing within the recycling stream (Das and Matthew, 1999).

E-Waste Compatibility Issues for Asphalt Binders and Mixtures

The issue of compatibility with integrating e-waste plastics with various other nonmetallic materials is crucial for its successful implementation. Yokoyama and Iji (1995) concluded that the compatibility between the e-waste fiberglass powder mixture and epoxy was a factor in improved mechanical performance. Morrison *et al.* (1994) also concluded that compatibility between the low temperature performance of plastic-rubber modified asphalt binders were a factor citing factors such as: interfacial strength between the dispersed and continuous matrix phases of the asphalt mixture. Indications of incompatibility between asphalt binders and e-waste plastics include modified based on the layers of plastic formed on the surface of the asphalt binder. Once the plastic forms a thick layer on the surface, the dispersion of plastic is difficult and may leads to premature failure (Morrison *et al.*, 1994). Cross linking is another indication of incompatibility between e-waste plastics. Anandhan *et al.* (2002) specified that the dynamic crosslinking between rubber and ABS seemed to play a part in preventing oil deteriorating the rubber ABS plastic blend. Small percentages of plastics and mechanical performance were correlated to compatibility and improved phase interaction in an investigation conducted by Balart *et al.* (2005)

Molecular weight of recycled e-waste plastic has an effect upon the compatibility and performance of materials blended with recycled e-waste plastics. Morrison *et al.* (1994) concluded that the high temperature performance of rubber-plastic modified asphalt binders were affected by the amount of dispersion present. Dissolved or fine particles with high weight molecules has great effect on asphalt binder creep properties (Morrison *et al.*, 1994). The author also specified that well dispersed modified asphalt binders provide a better resistance to permanent deformation in asphalt mixtures (Habib *et al.*, 2011). In contrast, asphalt mixture with a lower molecular weight polymer additives can be blended easier, but it does not contribute to the properties of asphalt binder as for high molecular weight additives (Aglan, 1993). In order to control the molecular weight of PP, Das and Patil used free radical initiators to initiate a chain scission process. The free radical initiators are peroxides which are catalyst to the degradation process at controlled rates for plastic palletization and where resin makers can control plastic degradation such as PE (Das and Matthew, 1999). As reaction times increase, it improved the tensile strength and intermolecular interaction along with a likely increase in molecular weight over a period of time (Das and Matthew, 1999). Das and Patil concluded that the reduction in molecular weight of PP was a success using free radical initiators and solvents (Das and Matthew, 1999). Lee and his team also worked with SBS, a common modifier used in polymer modified asphalt, to improve aging resistance using free radical initiators (Li *et al.*, 2010). In the investigation, double bonds in the poly butadiene segment of SBS is susceptible to aging, therefore free radicals formed from antioxidants break the double bonds at high temperatures leading to a cross linking or scission reactions making carbon-peroxide or carbon-carbonyl bonds (Li *et al.*, 2010). Colbert and You (2012b) also conducted an assessment using free-radical initiators to promote compatibility between ABS and HIPS e-waste plastics and asphalt binders. The free radical initiation process is shown in Fig. 5.

Measuring sieves and light microscopy were also used to evaluate the compatibility between asphalt binder and various waste plastics (Al-Hadidy and Yi-qiu, 2009b). FTIR is used to determine compatibility for e-waste plastics by giving information about the composition in differences between the molecular phases and looking at coarse microstructures (Achilias *et al.*, 2009, 2010). Assessment was carried out by Arnold *et al.* using FTIR to determine the compatibility of recycled plastic e-waste materials (Arnold *et al.*, 2010). Table 2 shows the various FTIR frequencies which are used to analyze typical e-waste thermoplastics within asphalt pavement applications.

Recently Mohd Hasan *et al.* investigated the effect of free radical reaction on the e-waste modified asphalt binders using ABS, ABS-PC, and HIPS plastics with cumene hydro peroxide. The result of this investigation indicated that the addition of initiator has significantly improved asphalt mixtures resistance to rutting (Mohd Hasan *et al.*, 2016).

Other Potential of E-Waste Plastic: Flame Retardant

Flame retarder is a typical component used within e-waste product that is designed to promote the use of thin plastic walls in electronic coverings and reduces the overall amount of plastic for electronic equipment, such as ABS and HIPS (Dawson and Landry, 2004). Electronic appliances with flame retardant include personal computer monitor housings, CPU's, circuit boards, plastic parts, printers, copiers, and laser jet printers, to prevent against high temperature spikes which may occur due to the high voltage supply for electronic equipment (Fisher *et al.*, 2005). In an investigation by Fisher *et al.* (2005) it is reported that 30% or all electrical and electronics products have flame retardants and 12% or all plastics used within the electronics industry have brominated flame retardants (BFR). The (BFR) is popular because of the versatility of applications that they can be used for in fire

Fig. 5 Hydro peroxide initiator polymerization of electronic waste plastics to asphalt binders.

Table 2 Approximate absorption wavenumbers for FTIR analysis for e-waste plastic modified asphalt binders

Functional group	Formula	Absorption wavenumbers (cm^{-1})
Carbonyl	$\text{C}=\text{O}$	1740–1690 (Stretching) indication of oxidation (Karlsson and Isacsson, 2003)
Aromatic and Hetero-aromatic rings		1600 ($\text{C}=\text{C}$ ring stretching) 900–600 ($\text{C}-\text{H}$ bending) (Karlsson and Isacsson, 2003)
Sulphoxide	$\text{S}=\text{O}$	1055–1030 (stretching) (Karlsson and Isacsson, 2003)
Methyl (aliphatic)	CH_3	2962, 2872 (Stretch), 1450, 1380 (bending) (Karlsson and Isacsson, 2003)
Methylene	CH_2	2926, 2853 (Stretch), 1465, 720 (bending) (Karlsson and Isacsson, 2003)
Hydroxyl	(OH-)	3250 (for indication of possible ABS degradation) (Balart et al., 2005)
Poly-acrylonitrile	$(\text{C}_3\text{H}_3\text{N})_n$	2236 (Arnold et al., 2010)
Poly-butadiene	C_4H_6	967 (Arnold et al., 2010)
Benzene rings		1602 from polystyrene (Arnold et al., 2009)

reduction, recyclability of plastics using BFR's, and the widespread documentation on the material properties and performance (Nnorom and Osibanjo, 2008).

The European Union has instituted regulations in 2006 to reduce the amount of brominated flame retardants to 0.1% of (polybrominated biphenyl (PBB) and polybrominated diphenyl ether (PBDE)) flame retardant types where the majority of these flame retardants occur in older electronic appliances (Khan et al., 2007). The pressure to reduce halogenated flame retardants has led to the increasing use of metal shielding and a shift from using ABS-PC plastics to ABS and HIPS plastics (Dillon, 1999). The PBDE contained within e-waste plastics as flame retardants do not have a strong chemical bond between the flame retardant and plastic matrix posing a leaching concern with disposal of e-waste plastics (Robinson, 2009). Recycling options for brominated flame retardants include mechanically separating e-waste materials containing BFR, or burning these components for energy recovery (Dawson and Landry, 2004). A problem with incineration of BFR is the toxic ash produced into the atmosphere (Santos et al., 2010). A harmful byproduct of waste printed circuit boards which are incinerated is hydrogen cyanide, carbon monoxide, dibenzo-*p*-dioxins and dibenzo furans from incomplete burning of the waste printed circuit boards (Li et al., 2007).

E-Waste Plastic Research Gaps within the Asphalt Pavement Industry

A research gap that needed to be addressed is the use of recycled plastics such as e-waste plastic used along with virgin rubbers to improve the mechanical properties of bituminous materials (Anandhan *et al.*, 2002). Further research are crucial to be conducted include, characterization of e-waste plastics, and quantifying the environmental and economic end of life cost benefits accounting for economic uncertainties using e-waste plastic coverings (Masanet and Horvath, 2007). Future research efforts must identify efficient methods of recycling e-waste plastics, since they are not easily identifiable, although the recovered e-waste plastics have a reduced processing expense versus virgin plastics due to high volume of e-waste (Ching *et al.*, 1996). Other issues which must be taken into consideration for e-waste plastic recycling is to address the various levels of recycling efficiency between various types of e-waste plastics such as, ABS-PC, which is not as advanced as ABS or HIPS plastics, and not as appealing to plastics recyclers economically (Khan *et al.*, 2007). Another research topic that should be taken into consideration prior to other successful applications for recycled e-waste plastics is to evaluate the compatibility between the waste plastics and other raw materials such as asphalt concrete, Portland cement concrete, metals, and future recycled waste plastics (Dillon, 1999; Morrison *et al.*, 1994).

Conclusions and Recommendations

The current state of applications for e-waste plastics was reviewed within this paper and performance results for e-waste modified asphalt binders were discussed. This paper reviewed the current research gaps which researchers should consider in order to successfully integrate e-waste plastics in a sustainable manner for asphaltic concrete materials. Major challenges which hinder the use of e-waste plastics within asphalt pavement materials are e-waste plastic compatibility with asphalt binders and mixtures, the removal or mitigation of hazardous waste materials within e-waste plastic products, and the issue of flame retardants within e-waste. The states of art for recycling e-waste plastics within asphalt pavement applications were discussed. The following issues need to be addressed by future research efforts to successfully implement e-waste plastics within asphalt pavements:

1. The effectiveness of the polymer use to modify asphalt depends on the source and type of polymer and the compatibility that it has with asphalt binder.
2. Despite the many hazardous materials present within e-waste products, utilizing the nonmetallic plastic components of the e-waste avoids the major heavy metal found within e-waste.
3. Economical recycling procedures must be developed to successfully use the thermoplastic components within e-wastes for use as sizes needed for the modification of asphalt binders and for aggregate replacement.
4. Research indicates that the use of e-waste plastics improved the high temperature properties for asphalt binders and mixtures.
5. Low temperature performance of e-waste plastics for asphalt materials is inconclusive and future research efforts must concentrate on appropriate amounts of e-waste material to implement into pavement materials for maximum performance.
6. Future research efforts need to focus on agents or additives which can effectively provide compatibility between various e-waste plastics and bituminous materials.

Introduction

This review article presents the research outcomes published in various scientific journals on carbon emission from fossil fuel based power plants and manufacturing industries and targets to share with the concerned stakeholders to speed up R&D work for reducing carbon emission. To achieve the objective, the study is divided into two major parts. Firstly, collecting information on carbon emission paths from fossil fuel based power plants and manufacturing industries. The second part of the study is to collect information on the contribution made by engineering to reduce carbon emission from power plants and manufacturing industries. This study has covered the research papers published in the years between 1990 and 2018 on global carbon emission, global warming (GW) and roles of engineering in developing technology to mitigate climate change effects. Indeed, this document aims at identifying the effective technical measures that have been taken by various organizations to mitigate carbon emissions from those industries, particularly in view of complying with the Kyoto Protocol commitment in achieving economic and environmental sustainability.

Intergovernmental Panel on Climate Change (IPCC), International Energy Association (IEA), United Nation Environment Protection (UNEP) and some other organizations have tried to address this global warming potential (GWP) issue by reducing man-made carbon emission where temperature increase should be limited to well below 2°C above pre-industrial levels, and pursuing a 1.5°C target with aim to mitigate climate change effects. Basically, the efforts of these organizations are limited to developing policy and strategy relating to the reduction of carbon emission and climate change effects. Many modeling studies also covered numerous scenarios of economic, energy and population features relating to carbon emissions and climate science, but the contribution of engineering to this emerging field in reducing carbon emission is not well discussed in published papers. This scenario indicates a gap exists in climate science domain (Henderson *et al.*, 2017) and hence the review work is designed to fill up this major gap.

However, to achieve research goal, this review covers publications made to report on CO₂ and CH₄ emission from fossil fuel based power plant, and as well as major manufacturing industries such as cement, iron, aluminum, palm oil mill, textile, and water treatment industries.

Background of Review on Carbon Emission and Mitigation Technology

Sustainable development strategy has been formulated to meet the needs of the present without compromising the ability of future generations to meet their own needs; this fundamental philosophy is being challenged by current climate change due to higher level carbon density in the atmosphere. The various studies have revealed that in 2016, CO₂ concentration in the atmosphere was 404 ppm, which is about 7% higher than 2007 and even the highest levels in emission history (IPCC, 2014c; UNEP, 2015; Brown *et al.*, 2016). The IPCC states that, if no effective measure is taken to reduce carbon emission, the concentrations would likely to increase 450 ppm by 2050; and between 750 ppm and 1300 ppm by 2100 (Augusta Ayotamuno, 2016; IPCC, 2017a). It was also estimated that by 2100, this planet may experience global mean surface temperature increases of 3.7–7.8°C compared to pre-industrial levels. It is reported that the atmospheric CO₂ concentration must be kept under 450 ppm in order for the global average temperature well below 2°C pre-industrial levels and pursuing a 1.5°C target within 2100 (Henderson *et al.*, 2017).

The broad objectives for reducing carbon concentration within estimated limit is to mitigate climate change effects that can be noticed globally in the form of higher temperature growth, which could lead to greater food insecurity, shortage of potable water (Augusta Ayotamuno, 2016), diseases outbreak and natural disaster (Rogelj *et al.*, 2013). A large body of literature is available on

Table 1 Global GHG emission control in GtCO₂eq at more than 55% probability

2020	2025	2030	2050	2100
56	47	39	8	– 5
53–56	46–48	37–40	4–14	– 5 to – 3

Another path to control temperature increase well below 2°C by 2100 at probability more than 66%.

Table 2 Global GHG emission control in GtCO₂eq at more than 66% probability

2020	2025	2030	2050	2100
52	48	42	23	– 3
49–35	44–53	29–44	17–29	– 11 to 0

Note: IPCC, 2017a. 'Intergovernmental Panel on Climate Change'. IPCC, 2017b. 'Intergovernmental Panel on Climate Change Sixth Assessment Report (AR6) Products'. Available at: https://www.ipcc.ch/meetings/session44/l2_adopted_outline_sr15.

pathways that limit GW to below 2°C within least-cost pathways starting from 2020, which can be divided into two groups (IPCC, 2014c). One is the least-cost pathway of limiting GW to below 1.5°C by 2100 with a probability of more than 55%.

In order to limit temperature increase within 1.5°C through reduction of carbon concentration in the atmosphere, it needs a great deal of innovation in the aspect of low carbon emission technology (Schleussner *et al.*, 2016). It was predicted that carbon emission reduction technology would significantly reduce the risks and impacts of climate change (Peters *et al.*, 2015; UNEP, 2016). Advanced technology development for increasing energy efficiency at consumption point, and both carbon capture for storing (CCS) and carbon capture for usage (CCU) could contribute to reducing carbon concentration in atmosphere significantly (International Energy Agency, 2010; Chapman *et al.*, 2013; Cebrecan *et al.*, 2014; Peters *et al.*, 2015; Schleussner *et al.*, 2016). It was also suggested that a huge amount of inputs from engineering discipline are required to redesign industrial manufacturing process for retrofitting CCS and CCU technology for reducing carbon emission (Hammond *et al.*, 2011; Mukherjee *et al.*, 2014). On this background, this study was designed to collect available information and to disseminate on carbon emission from fossil fuel based power plants, manufacturing industries with emission mitigation technology developed engineers in order to meet goals listed in Tables 1 and 2.

Global Warming and Climate Change Scenario

The Global Warming Potential (GWP) is a measure of GHG's impact on surface temperature (Henderson *et al.*, 2017) where the major GHG are CO₂, CH₄, and N₂O (IPCC, 2014c). The GWP is an indicator used to measure the effect of carbon emission on global surface temperature increase in a scale of 25, 100, and 500 years. In many studies, GWP of CH₄ is considered 25, N₂O is 360 with respect to CO₂. It implies that the effect of CH₄ in climate change is 25 times more than CO₂ (Scheehle and Doorn, 2001; Mukherjee *et al.*, 2014). However, it was reported that carbon concentration (CO₂eq) in the atmosphere is the main cause of increasing surface temperature and climate change (Chapman *et al.*, 2013). The various studies revealed that CO₂ concentrations in the atmosphere were 354.19 in 1990, 365.48 in 2000, 385.34 in 2008, 404 ppm in 2016. And it was also reported that carbon concentration would be 450 ppm in 2050 and 750 ppm in 2100 (IPCC, 2014c; UNEP, 2015), which will contribute to increasing surface temperature (Rogelj *et al.*, 2013; Henderson *et al.*, 2017). The historical data on carbon emission in the atmosphere is presented in Fig. 1 which indicates that carbon emission is increasing with time (EDGAR, 2014; IPCC, 2014c).

The carbon emission is a man-made issue relating to industrial development for economic growth maximization (EPA, 2010; Tol, 2018); which speed up GW. The GW is already underway with consequences that must be faced now, and as well as will appear in future. The GW is already bring changes in the Earth's physical, chemical and biological processes, and now its effect has appeared in every continent of the globe including societies and the natural environment (Georgakakos *et al.*, 2014). However, the climate change indicators stated in published papers are rising sea levels, shrinking glaciers dimensions; increasing surface temperatures, severe rainstorms and frequent droughts globally (IPCC, 2014a). Though it is difficult to quantify the impacts of climate change but it is believed to have major impact on the growth rate of the global economy, which may drag more people into poverty by inflicting severe damage on infrastructure and loss of productivity, in that climate situation, people may be obliged to migrate if they cannot cope with the resulting costs of climate change (Gosain *et al.*, 2006; Baig and Yousaf, 2017).

Fig. 1 The historical data on carbon emission. Reproduced from EDGAR, 2014. Emission Database for Global Atmospheric Research (EDGAR), release version 4.2, 2012. Emissions database for Global Atmospheric Research. doi:10.2904/EDGARv4.2; IPCC, 2014c. 'Climate change 2014 synthesis report summary chapter for policymakers', IPCC, p. 31. doi:10.1017/CBO9781107415324.

Global Inventory of Carbon Emission

It is evident that global carbon emission has increased at a steady rate of 1.3% during the period of 1970–2000; 2.2% per year during the period 2000–2010; 3.5% during the year 2010–2011, and 1.8% in the year 2012–2013 (EDGAR, 2014). The major primary sources of the carbon emissions are two: electricity production by the burning of fossil fuels namely coal, oil, gas, and MSW. And manufacturing industries (IPCC, 2007; EPA, 2010). The other sources are the clearing of forests, agricultural practices, transportation which is related to global economic growth (Dahe, 2014; IEA, 2017b). It was also reported that as of 2015, the two largest economies of the world are the major carbon emitters, where China accounted for 6.6 tCO₂eqyear⁻¹ and USA at 15.5 tCO₂eq year⁻¹, which is about 13% higher than 1990 (EPA, 2017). However, to meet the economic growth of these economies, they are planning to set up more power plants and manufacturing industries, which will contribute to increasing emission rate further (Chang, 2010; Habib *et al.*, 2013; Rogelj *et al.*, 2013).

Sources of Global Warming Potential

The major components of GHG are CO₂, CH₄, N₂O and Fluorinated gases (F-gases), which are responsible for global warming and climate change (Ben Abdallah *et al.*, 2013). The sources of these gases are power generation from fossil fuel, decomposition of biomass, deforestation, water treatment industries and agriculture activities (Gschrey *et al.*, 2011; Baig and Yousaf, 2017; IPCC, 2017a).

In GHG, the contents of carbon dioxide in the atmosphere is about 65%. The major sources of CO₂ are the burning of fossil fuels (Gschrey *et al.*, 2011; IEA, 2016). The methane content is the second largest in GHG after CO₂, which accounted for 16% of global emission. The major sources of CH₄ are the agricultural waste, MSW landfilling, waste biomass decomposition, wastewater treatment and animal litter. The effect of CH₄ on GWP and climate change is about 25% higher than CO₂ (IPCC, 2003; Yacob *et al.*, 2006; Liu *et al.*, 2016).

Nitrous oxide is also a part GHG in the atmosphere, and its contribution in GHG is about 6%. The major sources of N₂O emission are agricultural activities, such as fertilizer use, fossil fuel combustion, and wastewater treatment (Debruyne *et al.*, 1994; Wu *et al.*, 2018; Yao *et al.*, 2018). Fluorinated gases have a minor share in GHG. The sources of this gas are Industrial processes, refrigeration, and the use of the variety of consumer products contribute to generating F-gases including hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride SF₆ (IPCC, 2014d; Lee *et al.*, 2017).

However, in a report, IEA stated that the heavy industries like cement, Iron, and Aluminum are significantly responsible for GWP (IAI, 2009a; International Aluminum Institute, 2009b; Liang *et al.*, 2012; IEA, 2016).

Carbon Emission Sources

Begum *et al.* (2015) and fifth assessment report of IPCC (2014) had stated that carbon emission growth is positively associated with global economic growth (IPCC, 2014a). It has been also stated that growth of fossil fuel based power plants for supplying electricity to meet demands from manufacturing industries and other economic activities are the main reasons of global carbon emission growth (Habib *et al.*, 2013; IPCC, 2017a; Ozturk and Acaravci, 2010; Fan *et al.*, 2015). The evidences published in scientific journals show that the growth in world energy demand from fossil fuels has played a key role in the upward trend of CO₂ emissions (IPCC, 2014b).

The Inventory Carbon Emission From Fossil Fuel Based Power Plant

The global total electricity production was 22,433 TWh in 2014; and was 25,570 TWh in 2017, which encompasses the primary energy source (PES) such as coal at 39%; gas at 22%, and oil at 5% (IEA, 2016). Since the Industrial Revolution until 2017, annual

CO₂ emissions from fuel combustion are increasing at a significant rate. Various studies revealed that about 40% of total global GHG have been contributing to electricity production (IPCC, 2003; Henderson *et al.*, 2017). Global energy-related CO₂ emissions rose by 1.4% in 2017, which accounted for 46Gteq (Habib *et al.*, 2013; Le Quéré *et al.*, 2016). The data released by the USA Department of energy show that the share of global GHG emission from energy sector is about 42% (Habib *et al.*, 2013; Moazzem *et al.*, 2013). The EDGA published data, which show that global GHG emission from energy sector was 2.1 GtCO₂eq in 1950; 4.2 GtCO₂eq in 1965, 6.3 GtCO₂eq in 1975, 8.4 GtCO₂eq in 1990, 10.5 GtCO₂eq in 2000, 13.8 GtCO₂eq in 2015 and 19.32 GtCO₂eq in 2017 (EDGAR, 2014; Le Quéré *et al.*, 2016).

Carbon emission from coal-fired power plant

The major percentage of electricity has been produced from this primary energy sources (Andres *et al.*, 1996; IPCC, 2007), while Coal is the least efficient fossil fuel in terms of energy output per unit of CO₂ emission. As stated by U.S. EPA, (2000) that the coal-fired power plants are taking a significant percentage of share in producing electricity where its share in generating CO₂ per kilowatt hour is higher compared to other fossil fuel (Hammond and Spargo, 2014; U.S. EPA, (2000)). IEA stated that coal represented about 28% of the world total primary energy source (TPES), and it accounted for about 15% of the global CO₂ emissions (Ostrowski, 2010; Liang *et al.*, 2012). The average GHG emission rate from burning coal for producing electricity is 0.85 tCO₂eq(kWh)⁻¹ (IPCC, 2007; Lindner *et al.*, 2013). Though by adding CCS and increasing energy efficiency in coal-fired plants, the emission reduced to about 0.5 tCO₂eq/(kWh)⁻¹ (Baig and Yousaf, 2017). The emission history on coal-fired energy revealed that global emission was 8,533 Mt in 2000, 11,360 Mt in 2005, 13,916 Mt in 2010, 114,148 Mt in 2013 (Maryland and Rotty, 1984; IPCC, 2006; EDGAR, 2014). According to the International Energy Agency, the electricity production and GHG emission from coal will increase further about 30% by 2035 due to electricity production capacity increase in this sector.

Carbon emission from biogas fired power plant

Two ways in which natural gas mainly CH₄ is emitted to the atmosphere are through gas transportation and burning of gas for electricity production. However, CH₄ has 25 times higher GWP than compared to CO₂. The CO₂ emission from Gas Turbine Power Plant (GTPP) ranges from 0.4 tCO₂eq(kWh)⁻¹ to 0.6 tCO₂eq(kWh)⁻¹ (Hosseini and Wahid, 2013), which is next higher level of emission compared to coal-fired based energy production (Scheehle and Kruger, 2006). Though by the installation of CCS technology in GTPP, the emission reduced to about 150 gCO₂(kWh)⁻¹ (Hosseini *et al.*, 2013). The emission history on gas-fired energy revealed that total global emission from GTPP was 4712 Mt in 2000, 5416 Mt in 2005, 6233 Mt in 2010, 6222 Mt in 2013, 7.622 Mt in 2015 (Poeschl *et al.*, 2012).

Carbon emission from petroleum oil based power plant

Combustion of petroleum oil for electricity production is one of the top listed sources of CO₂ emissions (Yeh *et al.*, 2017a,b), and estimated emission range is from 3.5 kgCO₂eq(kWh)⁻¹ to 500 kgCO₂eq(kWh)⁻¹ (Burnham *et al.*, 2012; EIA, 2014). The emission history on oil-fired energy revealed that total global emission from oil was 10,425 Mt in 2000, 11,254 Mt in 2005, 11,475 Mt in 2010, 11,793 in 2013, 13.612 Mt in 2015 (EDGAR, 2014).

Emission from municipal solid waste

Municipal solid waste (MSW) is a potential CH₄ emitter, and significantly responsible for enhancing global warming and climate change (Manfredi *et al.*, 2009). Once MSW is disposed into landfills, it undergoes aerobic decomposition process over years, and continue in methanogen activities (Møller *et al.*, 2009; Manfredi *et al.*, 2009). It was reported that CH₄ yield from MSW landfill is up to 0.5 t/t MSW (range 0.1–0.5 t per ton of MSW) (Metz and Davidson, 2007; Møller *et al.*, 2009; Monks *et al.*, 2009; Siddiqui and Khan, 2011; Kumar and Sharma, 2014). A study on MSW reported that CH₄ emission from this sector is a major contributor in GW with a share of about 18% (IEA, 2016; Xydis *et al.*, 2013). In an estimate EPA reported that CH₄ concentration in air was about 68 Mt in 2008, and it would be 130 Mt in 2018, 220 Mt in 2025; 550 Mt in 2030 (Mathews, 2007).

Carbon Emission From Manufacturing Industries

Industrial processes are highly energy intensive and currently account for one-third of global energy use (IEA, 2009; Allwood *et al.*, 2010). It is estimated that around 70% of required energy for industry operations are supplied from the burning of fossil fuels, which make up 40% of total global CO₂ emissions (Allwood *et al.*, 2010). It was also evaluated that emission from the manufacturing process is about 7% (IEA, 2009; Allwood *et al.*, 2010). However, both energy production and manufacturing process are significantly responsible for climate change due to the significant amount of carbon emission.

There are three ways in which carbon is emitted from manufacturing industries. The first route is by the combustion of fuel for producing electricity to operate plant machinery. The second route is by steam production from fossil fuel (IEA, 2017a; IPCC, 2017b). The third route of emission is by the use of carbon-based raw materials for producing product, for example, chemical reaction to convert limestone (CaCO₃) into lime (CaO) (Alsop, 2005; Tol, 2018). The major carbon-emitting industries are Cement, Iron, agriculture, Aluminum, Petrochemicals; and water treatment industries. The estimated GHG from manufacturing industries was about 1.75GtCO₂eq in 2000, 2.33GtCO₂eq in 2015 and 3.22GtCO₂eq in 2017 (EDGAR, 2014); and it would be increased further with manufacturing growth.

Carbon emission from cement industry

Cement production is an energy and carbon-intensive process (Robbie, 2017). In fact, there are two ways by which CO₂ are generated from cement production process. The first one is the burning of fossil fuels to produce electricity and steam for plant operation. The second one is chemical reactions involved in the production of clinker. In the clinker production process, limestone (as MgCO₃ and CaCO₃) disintegrates to produce CaO or MgO, which is known as calcination (Alsop, 2005; Andrew, 2017).

The electrical power consumption of a cement plant is around 1200 kWh t⁻¹ cement (Bakhtyar, 2017; Bakhtyar *et al.*, 2017). This industry emits up to 0.9tCO₂eqt⁻¹ cement [range 0.5–0.9tCO₂eq] (Keeling, 1973; Mahasenan *et al.*, 2003). The global emission data revealed that the contribution to global emission from cement plant was 828.7 Mt in 2000, 1173 Mt in 2005, 1642.82 Mt in 2010, 2031 Mt in 2013, 2213 Mt in 2015 (Keeling, 1973; Tol, 2018; EDGAR, 2014).

Carbon emission from iron and steel industry

International Energy Outlook 2012 reported that the iron and steel industry accounted for about 10% energy consumer of total manufacturing sector (Li *et al.*, 2016). This sector is the second largest industrial CO₂ emitter due to its energy-intensive process and reliance on carbon-based fossil fuels (Yu *et al.*, 2015). Two ways carbon emits from Iron industry such as electricity production for the operating plant machinery, and from Iron production process. Coal and gas-fired power plants are the main sources of electricity and heat supply to Iron and steel process plant (Wou *et al.*, 2015). It is found that from a traditional scrap/electric arc furnace, the carbon emission is about 0.4tCO₂eqt⁻¹ crude steel; and from the integrated blast furnace is up to 1.8tCO₂eqt⁻¹ crude steel. From a basic oxygen furnace process, the emission is up to 2.5tCO₂eqt⁻¹ crude steel (LBNL, 1999). Global carbon emission data shows that the emission from Iron industries was 2.3 Gt in 2016. The projected contribution from this sector to global CO₂ emissions would be about 4.5 Gt in 2050 corresponding to estimate of 3-billion-ton steel production (Allwood *et al.*, 2010).

Carbon emission from aluminum industry

Aluminum processing consumes about 1400 kWh/t Aluminum ingot production (International Aluminum Institute, 2006). The IPCC has marked Aluminum processing as a major GHG emission-intensive industry; and has emphasized to reduce emission from this industry from 50% to 85% by the year 2050 (IAI, 2013; Zeng *et al.*, 2015; Paraskevas *et al.*, 2016). It was estimated that 65% emissions are caused mainly electricity production required for operation of plant machinery. And the other 35% is from aluminum production process (IPCC, 2007; Paraskevas *et al.*, 2016). According to the IEA's indicative statistics, when coal-fired electricity used for Aluminum processing, it contributes about 0.98 kgCO₂eq(kWh)⁻¹ (Paraskevas *et al.*, 2016), whereas during the use of natural gas-fired plants emit 0.54 kgCO₂eq(kWh)⁻¹ (IAI, 2013). Accordingly, emission from Aluminum processing is 1.3CO₂eq/t Aluminum when using coal for energy production; and it could be about 0.73CO₂eq/t Aluminum when using gas for energy production (Zhang *et al.*, 2015). It was also reported that contribution from Aluminum production industry to total global GHG emissions was 0.45 GtCO₂eq in 2007, which was approximately 1.0% of the global GHG emissions (IAI, 2013; Zhang *et al.*, 2015; Paraskevas *et al.*, 2016).

Carbon emission from textile industry

Textile is an important industry in the world economy, and this sector has marked as a medium level energy user and GHG emitter (Clark, 2007; Islam and Khan, 2014). GHG is emitted from this industry to the atmosphere in three different ways. The first route of carbon emission is the production of electricity to operate the process machinery. The second route of emission is textile processing. And the third route of emission is wastewater treatment process (Guleryuz, 2011; IPCC, 2013; Toprak and Anis, 2017). It is estimated that the annual textile production was 60Mt in 2016 and it would be 97.8Mt in 2018 and emission will increase accordingly (Toprak and Anis, 2017). The wastewater treatment is another carbon emission intensive part of the textile industry which emits CO₂, CH₄, and N₂O. The CH₄ emission level depends on COD concentration in wastewater (Scheehle and Doorn, 2001; Shahabadi, 2008; Robbie, 2017) and COD reduction process (El-Fadel and Massoud, 2001; Campos *et al.*, 2016). In major cases, the source of CO₂ emission is from the usage of CaCO₃ in wastewater treatment process which breaks down to CO₂ (Campos *et al.*, 2016).

In knitwear process, about 60% emissions are caused by steam production required in dyeing process (Chen, 2013; Hridam *et al.*, 2016). It has been reported that thermal energy requirement is about 22 MJ m⁻¹ of fabric, and electrical energy consumption in process is up to 0.5 kWh m⁻¹ fabric (range 0.15–0.5 kWh m⁻¹) (Guleryuz, 2011; IPCC, 2013; Toprak and Anis, 2017). The average emission from fabric dyeing process is up to 1.3kgCO₂eq/kg knitted fabric (range 0.8–1.3 kgCO₂eq). It was reported that starting from spinning, knitting, dyeing, finishing, cutting, sewing, plus transportation final products to distributions center, emission could reach up to 12.5 kgCO₂eqkg⁻¹ fabric (Annual report, 2016). However, GHG data from 2012 to 2017 revealed that total emission from textile industry was 8500 Mt year⁻¹ to 1200 Mt year⁻¹ which accounted for 3% of global industrial emission (UNEP, 1993; Annual report, 2016).

Carbon emission from palm oil industry

Increasing palm oil demands in global market is positively associated with GWP due to its carbon emission intensity (Kaewmai *et al.*, 2013; Oosterveer, 2014). Nowadays, this industry becomes a global carbon emission issue. It was reported that CH₄, CO₂, and N₂O have a large share in the total global warming potential (Zutpen and Van, 2005). Palm oil industry emits GHG in three ways. The first route of emission is from burning of fuel in palm oil harvesting machinery. The second route is emission from production of electricity to operate the process. And the third route is emission from wastewater treatment process called POME.

The total GHG emissions from three routes are up to about 30 tCO₂eqt⁻¹ CPO (Zutpen and Van, 2005; Damen and Faaij, 2006); and among this CH₄ emission is significantly harmful (Renewable fuel Agency, 2008; Ng *et al.*, 2011). It has been reported that reported that CH₄ emission potential of POME is about 9 kgt⁻¹ FFB, which equivalent to about 18.3 m³CH₄t⁻¹ POME (Renewable fuel Agency, 2008). It has been also reported that emission rate is about 190 kgCO₂eqt⁻¹ FFB (Ng *et al.*, 2011; The statistics portal, 2018).

In a report, Chynoweth *et al.* (2000) had stated that CH₄ emission could be reduced from 9.0 m³t⁻¹ POME to 5.5 m³t⁻¹ POME by using efficient CCS and CCUS technology (Chynoweth *et al.*, 2000). However, Sridhar and Adeoluwa (2009); and Ng *et al.* (2011) reported that biogas (CH₄, CO₂, and H₂S) yield from POME is up to 28 m³t⁻¹ POME (Sridhar and Adeoluwa, 2009; Ng *et al.*, 2011). Based on (Wicke *et al.*, 2008) and (Zah *et al.*, 2007) estimate, the average emission from palm oil industries found 30 tCO₂eqt⁻¹CPO (Zutpen and Van, 2005; Damen and Faaij, 2006). It was also reported that the contribution of palm industry to global emission was 1569.6 tCO₂eq in 2013, 1680 tCO₂eq in 2014, 1779 tCO₂eq in 2015, 1824 tCO₂eq in 2016 and 1854 tCO₂eq in 2017 (Zutpen and Van, 2005; Wicke *et al.*, 2008).

Carbon emission from water treatment industry

GHG emissions from wastewater and water treatment industries have caused a threat to global sustainable development agenda (Scanlan *et al.*, 2008). The effluent of textile, tannery, POME, chemical, and municipal wastewater are the top ranking carbon emitters. In wastewater treatment process, GHG emits in two ways. The first way of emission is the burning of fossil fuel to produce electricity for the operation of plant machinery (Khandare, 2015). Shaw *et al.* (2008) stated that at the second level, CH₄ and CO₂ emit from treatment process such as from anaerobic reactor (Shaw *et al.*, 2008; Khandare, 2015). A few research reports indicated that wastewater treatment is a potential anthropogenic CO₂ emission source, which is significantly responsible for GWP (Shaw *et al.*, 2008; Khandare, 2015; Hanaki *et al.*, 2001; Sahely *et al.*, 2006). It was also reported that energy consumption in water treatment process is up to 075 kWh t⁻¹ wastewater, which generates up to 1.3 kgCO₂eqm⁻³ water (Choorit and Wisarnwan, 2007; Haridas *et al.*, 2016; Toprak and Anis, 2017).

Engineering in Carbon Emission Reduction From Industries

Engineering contribution in development and implementation of carbon emission reduction technologies have been highlighted in various published papers. It was also stated that a huge amount of inputs from engineering have been employed to develop technologies in order to reduce carbon emission. In this aspect, the major involvement of engineering are: increasing of electricity output efficiency in power plant (Markusson *et al.*, 2012a,b; International Energy Agency, 2017), retrofitting low carbon energy supply to industries (EPA, 2017), using higher energy efficient machinery (Kuo and Wu, 2015), and, using CCS and CUS technologies (Peters *et al.*, 2015) in power plants and manufacturing industries. The cost-effective technologies installation at manufacturing industries for carbon emissions reduction is regarded as a top listed contribution from engineering. The using of low carbon-based raw materials in producing new products, increasing product life cycle, reducing material requirements through efficient product design, and recycling waste materials in new product developed are the key contribution from engineering profession in achieving environmental sustainability (EPA, 2017).

Engineering in Carbon Emission Reduction by Increasing Energy Efficiency

The major involvement of engineering in emission reduction by increasing energy efficiency are: increasing of electricity output efficiency in power plant (Markusson *et al.*, 2012a,b; International Energy Agency, 2017), retrofitting low carbon energy supply to industries (EPA, 2017); and, using the CCS and CUS technologies (Peters *et al.*, 2015) in power plants and manufacturing industries. Developing higher energy efficient machinery and using in industry are recognized as key contribution of engineering to slowdown of GW (Kuo and Wu, 2015).

Engineering in Developing Low Carbon Based Raw Materials for Product Processing

Developing product processing with low carbon-based raw material has appeared a significant contribution to reducing carbon emission (Bakhtyar *et al.*, 2017). For example, Fly-ash or cementations materials or calcination materials have utilized directly in the cement kiln as a replacement of MgCO₃ and CaCO₃, which have contributed to reducing 40% energy consumption in the production process with 50% less CO₂ emissions (Mahasenan *et al.*, 2003; Bakhtyar *et al.*, 2017).

Engineering in Developing Carbon Capturing and Storing Technology

A number of technologies have been developed for carbon emission reduction from power plants and manufacturing industries including CCS, CCU, bio-char techniques, mineral carbonization and biological techniques (Falkowski *et al.*, 1998; Wang *et al.*, 2015). However, CCS/CCUs are engineering-intensive activities, which appeared to be the potential way of reducing GHG emission from power plant and manufacturing industries. The potential routes for CCS from power plant and manufacturing

industries are: capturing from emission sources is the first step. At second step carbon transport to depleted oil and gas fields. The third step and final step is to inject carbon into saline aquifers for storing (Hammond *et al.*, 2011; Henderson *et al.*, 2017). In this process around 90% of operational carbon emissions can be captured; and albeit with an additional energy cost of 16%–20% (Davison, 2007; Hammond *et al.*, 2011; Treasury, 2017). For example, a coal-fired power plant with CCS, the carbon emission rate is about $0.12 \text{ kgCO}_2\text{eq(kWh)}^{-1}$. Whereas, a plant without CCS, the emission rate is about $0.96 \text{ kgCO}_2\text{eq(kWh)}^{-1}$ (IPCC, 2014c, 2017b; Leung *et al.*, 2014; UNEP, 2015).

Engineering in CCS technology implementation at pre-combustion stage of power plant

Three major ways are available for capturing clean CO_2 gas from pre-combustion stage power plants (El-Fadel and Massoud, 2001). The Sorbents and sorbent-enhanced water gas shift technology, Oxy-fuel combustion process, and membrane separation are the proven technologies used in power plants for carbon capturing (ECN, 2013; Spigarelli and Kawatra, 2013). Sorbents and sorbent-enhanced water gas shift technology is a pressure swing cycle and in this technology, hydro-talcite sorbent has appeared as an efficient media (Da Costa *et al.*, 2013). The basic principle of an Oxy-fuel process is of using oxygen in pre-combustion stage of coal fire instead of air. This is an advanced novel technology has the potential to capture over 98% of operational CO_2 emission from power plant (Anderson and Newell, 2004; Bjerger and Brevik, 2014; Lockwood, 2017). Membrane-based CCS is an engineering and cost-intensive process, and dedicated polymer membranes are well suited to separate CO_2 from exhaust gas stream. In this process, about 90% CO_2 retain in high-pressure side of the membrane (Da Costa *et al.*, 2013). This process offers a few advantages including reducing chemical use in water treatment process of power plant (Anderson and Newell, 2004; Lockwood, 2017).

Engineering in CCS technology implementation at post-combustion stage of power plant

Post-combustion carbon capture technique is applied to separate CO_2 from flue gases from the conventional fossil fuel-fired power plant. This technology has reached nearly a mature stage (Inventys, 2009), and could easily be retrofitted at the relatively low cost to existing power plant (ECN, 2013) by keeping combustion process unchanged. In this process, heat from flue gas is recycled to increase thermal efficiency at a CO_2 production cost below $\$30 \text{ t}^{-1}$ (Anderson and Newell, 2004). It was suggested for further R&D to increase performance of CCS technology in order to reduce operating cost (Anderson and Newell, 2004; Lockwood, 2017).

Engineering Efforts for Carbon Reduction From Coal-Fired Power Plants

Cebucean *et al.* (2014) stated that CO_2 emissions from coal-fired power plants are being reduced in three ways, which are engineering-intensive activities. It was reported that the carbon emission from the coal-fired power plant was reduced from $0.9 \text{ tCO}_2\text{eq(MWh)}^{-1}$ to $0.55 \text{ tCO}_2\text{eq(MWh)}^{-1}$ by increasing thermal efficiency from 33% to 40% (Cebucean *et al.*, 2014).

In the coal-fired power plants, CCS technology has also been successfully implemented in both pre and post combustion stages, which contributed to reducing about 90% carbon emission (Inventys, 2009; Liu *et al.*, 2016; Lockwood, 2017). It was reported that in a coal-fired power plant with CCS technology, the emission rate was only $0.12 \text{ tCO}_2\text{eq(kWh)}^{-1}$ (Cebucean *et al.*, 2014; Lockwood, 2017) at a cost of $\$25 \text{ t}^{-1}\text{CO}_2$ (Davison, 2007; Treasury, 2017). It was also reported that application of CCS may increase coal consumption by 25% with electricity production cost up to 50% (Markusson *et al.*, 2012a,b). Arias *et al.* (2013) and Hilz *et al.* (2015) had addressed this issue and reported that they managed to capture CO_2 at a cost of $\$20 \text{ t}^{-1}\text{CO}_2$ by using calcium looping in CCS technology (Arias *et al.*, 2013).

Engineering Efforts for Carbon Emission Reduction From Gas-Fired Power Plant

The carbon emission ranges from a biogas-fired power plant is $0.4 \text{ tCO}_2\text{eq(kWh)}^{-1}$ to $0.6 \text{ tCO}_2\text{eq(kWh)}^{-1}$ (Scheehle and Kruger, 2006; Laboratory, 2015) at a thermal efficiency of 33% to 39%. By installing of waste energy recycling technology, this emission is currently reduced by 27% through increasing thermal efficiency from 39% to 57% (Campanari, 2002; Report, 2012; Hosseini *et al.*, 2013). Molten Carbonate Fuel Cell (MCFC) seems to be another solution to carbon emission problem of the gas-fired power plant. Jarosław Milewski stated that MCFC has effectively used to reduce 73% CO_2 emissions from a Gas Turbine Power Plant (Campanari, 2002; Sánchez *et al.*, 2011; Milewski and Bujalski, 2012) where the recorded emission was only at $135 \text{ kgCO}_2\text{eq(MWh)}^{-1}$ (Report, 2012; Clemente, 2016). However, Carbon capture, use, and storage appeared to be technologically feasible for solving the carbon emission problem though it increases energy production cost by about 25% (Yeh *et al.*, 2017a,b; Cormos *et al.*, 2013; Anderson and Newell, 2004).

Engineering Efforts for Carbon Emission Reduction From Municipal Solid Waste Based Powerplant

Methane emission from MSW is reduced in two ways. One is engineered landfill for optimizing of the CH_4 formation. The second one is landfill gas capturing for WtE technology. It was reported that an engineered WtE plant could successfully reduce CH_4 emission from 0.5 tt^{-1} MSW to 0.2 tt^{-1} MSW (Morselli *et al.*, 2008).

Methane Capturing for electricity production have well established, and globally over 1000 landfills are operating, which contributes to reducing CH_4 emission significantly (IPCC, 2006). The EPA Landfill Methane Outreach Project reported that 2.6 Tg

CH₄ was captured and utilized in power plant for generating 9 billion kWh of electricity in 2005. In another estimate, it was reported that by the year 2030, methane capturing capacity would be 10.3 Tg globally (EPA, 2009). Barnstead and La stated that CH₄ emission reduction capacity through engineered WtE would be about 1800 tCO₂eq(GWh)⁻¹ by 2030 (Bernstad and La Cour Jansen, 2012). It was also stated that if at least 10% MSW is used engineered WtE, it could contribute to reducing about 30% (12 Tg) methane emission by 2030 (Bernstad and La Cour Jansen, 2012). It was also reported that higher CH₄ collection efficiency with CCS technology is economically and environmentally sustainable options but needs quality inputs from engineering (Rajaeifar *et al.*, 2017).

Engineering Efforts for Carbon Emission Reduction From Cement Manufacturing Plant

Carbon emission reduction from cement plant using CCS technology has appeared to be the sustainable procedure for reducing GW (Bakhtyar *et al.*, 2017; Olivier *et al.*, 2017). It was reported that three types of engineering inputs are employed to reduce carbon emission (Bakhtyar *et al.*, 2017).

The first engineering input is the use of indigenous materials and process technology in order to reduce CO₂ emission. For example; the fly-ash or cementations materials or calcination materials are utilized directly in the cement kiln as a replacement for clay or bauxite. This approach contributes to the reduction of 50% CO₂ emissions (Bjerger and Brevik, 2014). Moving from wet to dry process with calciner could also reduce up to 50% of requisite energy and almost 20% of CO₂ emissions in the cement production process (IEA, 2007a,b; Bjerger and Brevik, 2014). The second engineering input is the retrofitting of advanced technology into the existing plants for decreasing the use of MgCO₃ and CaCO₃, this approach contributes to reducing a significant amount carbon emission.

The third engineering inputs are the development and retrofitting of the cost-effective CCS technology in flue gas stream. It was reported CCS technology has been successfully utilized to reduce carbon emission from 0.50 tCO₂eqt⁻¹cement to 0.20 tCO₂eqt⁻¹Cement (Bjerger and Brevik, 2014).

Engineering Efforts for Carbon Emission Reduction From Aluminum Processing Plant

Few ways have been employed by engineers to reduce carbon emission from Aluminum processing. The most popular way is to use advanced technology to reduce energy consumption; in this regards, Norwegian engineering had made a successful progress (Bjerke *et al.*, 2004; Kuo and Wu, 2015). It is reported that carbon emission intensity from Aluminum industry was 4.0 tCO₂eqt⁻¹ in 1993; 1.3 tCO₂eqt⁻¹ in 2014. Indeed, this progress had made by increasing energy efficiency in the production process (Zhang *et al.*, 2015).

The second type of engineering inputs is the use of non-carbon anode which contributes to reducing energy consumption about 25% and resulting in a reduction of over 40% GHG emissions (IAI, 2009a; International Aluminum Institute, 2009b; Bjerger and Brevik, 2014). The third type of engineering inputs was the recycling of waste Aluminum in producing new products which contributed to reducing a significant amount of energy consumption and carbon emission (IAI, 2009a; International Aluminum Institute, 2009b). The fourth type of engineering inputs was the use of low carbon energy in the production process such as hydropower plant. It was reported that a plant with electricity from hydropower plant emission was 0.45 tCO₂eqt⁻¹Aluminum (Argonne, 2009; IAI, 2009a; International Aluminum Institute, 2009b), whereas it was 1.3 tCO₂eqt⁻¹ Aluminum when used coal-fired power plant.

Engineering Efforts for Carbon Emission Reduction From Iron-and Steel Industry

A significant achievement has made by engineers to reduce carbon emission from Iron and steel industry by using three methods; which contributed to reducing from 1.3 tCO₂eqt⁻¹ steel to 0.2 tCO₂eqt⁻¹ (Anderson and Newell, 2004; IEA, 2007a,b; Casillas *et al.*, 2015). Energy efficiency increasing in Iron and Steel production process appeared a significant achievement. In this process, best available technologies had been used for recovering waste thermal energy from flue gas and reused (Kuo and Wu, 2015; Seoane *et al.*, 2015). It was reported that in this process about 30% energy consumption had reduced and net emission appeared about 0.9 tCO₂t⁻¹ Steel instated of 1.3 tCO₂t⁻¹ Steel (LBNL, 1999).

Supplying low carbon energy from hydropower plants to iron and steel industries was considered a successful input from engineering for reducing about 60% carbon emission. The low car carbon energy supply has contributed to reducing emission from 1.3 tCO₂t⁻¹ Steel to 0.45 tCO₂t⁻¹ Steel (LBNL, 1999; UNIDO, 2011).

Another value-added engineering input into Iron and steel production process was of installing CCS technology. The CCS had applied in both pre and post combustion stage of fossil fuel based power plant used in iron and steel industries. The CCS contributed to reduce carbon emission about 90%. It was reported that a plant with CCS technology, the net emission appeared 0.15 tCO₂t⁻¹ Steel instead of 1.3 tCO₂t⁻¹ Steel (IEA, 2007a,b).

Engineering Efforts for Carbon Emission Reduction From Palm Oil Mill

Three engineering activities have recorded in published journals for reducing CO₂ and CH₄ emission from palm oil mills (Ng *et al.*, 2011; The statistics portal, 2018). The total carbon emission from palm plantation; oil refinery at mills for CPO production and

POME processing are accounted for $30 \text{ tCO}_2\text{eqt}^{-1}\text{CPO}$ (Zutpen and Van, 2005; Damen and Faaij, 2006) which reduced to about 40% by using engineered plant machinery (IPCC, 2009).

It has been reported and the using of advanced technology in palm oil industry energy consumption reduced from $90 \text{ (kWh)}^{-1}\text{CPO}$ to $50 \text{ kWh}^{-1}\text{CPO}$ which contributed to reducing 40% carbon emission (Ma *et al.*, 2010). The second and third ways of engineering inputs were of using anaerobic reactor for CH_4 capturing from POME treatment (Kaewmai *et al.*, 2013). The most effective anaerobic reactor developed and used are expanded granular sludge bed reactor (Oosterveer, 2014), up-flow anaerobic Sludge-Fixed film reactor and anaerobic Fluidized Bed single stage reactor (Zhang *et al.*, 2008).

Anaerobic reactor appeared as an efficient technology for methane capturing and using in electricity production. It was reported that CH_4 emission reduced successfully from $9.0 \text{ m}^3\text{CH}_4\text{t}^{-1}$ POME to $5.5 \text{ m}^3\text{CH}_4\text{t}^{-1}$ POME by using efficient CCS and CCUS technology. However, Sridhar and Adeoluwa (2009), Ng *et al.* (2011) reported that CH_4 and CO_2 capturing capacity of an anaerobic reactor is up to $28 \text{ m}^3 \text{ t}^{-1}\text{POME}$, which is high value-added innovation in engineering domain (Annual report, 2016).

Engineering Efforts for Carbon Emission Reduction Water Treatment Industry

Engineering efforts have been deploying in three ways to reduce carbon dioxide, methane, and nitrous oxide (N_2O) emission from water treatment industry (Borja and Banks, 1994; Scheehle and Doorn, 2001). One way of engineering inputs to reduce carbon emission is of increasing energy efficiency by installing advanced technology in water treatment plant. In this way, about 20% carbon emission has reduced from water treatment processing (Choorit and Wisarnwan, 2007). The second way of engineering inputs to reduce carbon emission is of installing anaerobic digester in the treatment process for capturing CH_4 (Seoane *et al.*, 2015). It has been reported that anaerobic reactor has successfully employed to capture over 90% CH_4 from water treatment plant (Hasanbeigi, 2010).

The third way of engineering inputs for carbon capturing is the employment of bio-engineering. Algae production in polluted wastewater has appeared a potential CO_2 sink (Falkowski *et al.*, 1998). It was reported that Algae have the ability to sequester about 40% CO_2 (Hasanbeigi, 2010). It was reported that Algae have the capability of sequestering CO_2 two times higher than terrestrial species.

Conclusion and Summary of Findings

This review article presents the research outcomes published in various scientific journals on carbon emission from fossil fuel based power plants and manufacturing industries. The study aims to share reviewed information with the concern stakeholders for enabling them to make a plan for conducting R&D towards reducing carbon emission for mitigating global warming.

Almost 90% papers studied for this review have stated that fossil fuel burning, energy inefficiency and using of carbon-based raw materials by some heavy industries are the main causes of carbon emission, which contributes to increasing global surface temperature. It was also reported that fossil fuel shall be replaced by low carbon energy in order to maintain carbon density in the atmosphere within 445 ppm for keeping temperature rise well below 2°C compare to pre-industrial development level.

The published papers have indicated that various technologies have developed and retrofitted into fossil fuel power plants and manufacturing industries for capturing carbon aiming to store and use in order to reduce carbon density in the air. It appears that installation of CCS technology is cost and engineering intensive activities, but its contribution to carbon emission reduction is significantly high.

It is also evident that CCS and CCU technologies are contributing to increase energy production cost, but dedicated R&D would be able to reduce cost to an acceptable limit. However, it was stated in various papers that cost of carbon reduction will offset by saving repair cost of infrastructure expected to be damaged due to climate change effects.

Introduction

Over the years, asbestos has been used as reinforcement material in brake lining production as a result of its good physical and tribological properties. However, recent studies have shown that asbestos poses a great health hazard which can result from its handling and breathing (NIH, 1989). As a result, it has lost its favor, resulting in the need to explore alternative materials. Hence, efforts by researcher have been geared toward finding a possible replacement for asbestos in the production of brake linings. These were exemplified by the work of several researchers who utilized other materials such as palm kernel shell (PKS), coconut shell, metal fibers, etc., for inclusion in brake lining in order to overcome environmental pollution (Ikpambese *et al.*, 2016; Fono-Tamo and Koya, 2013). Also, a non-asbestos friction lining material was developed by Ibhadode and Dagwa (2008) using an agro-waste material – palm kernel shell, as a reinforcement material. Palm kernel shell (PKS) which was used as a reinforcement material was selected due to its favorable properties which superseded other agro-waste. The developed automobile disk brake pads using the derived friction material and the test results obtained indicated that high wear rate was observed on the PKS pad at high vehicular speeds of 80 km h⁻¹ and above. Zaharudin *et al.* (2012) adopted Taguchi method to carry out a study on the effect of manufacturing parameters on the properties of friction materials. The parameters studied were molding pressure, molding temperature, and the molding time using semi-metallic friction materials and other additives. Physical properties such as hardness and specific gravity as well as tribological properties (wear and fade) were selected as responses and optimized. Molding pressure was observed to be the most significant factor that affected the physical and tribological properties.

Similarly, Bashar *et al.* (2012) carried out a study on the selection and production of composite brake pad by varying constituent compositions. Coconut shell powder was used in the study including other additives such as cast iron fillings, silica, epoxy resin, a catalyst, and an accelerator. Some of the tests conducted in the study included tensile strength, compressive, hardness, impact, wear, and corrosion. Results obtained were in close agreement with commercial-based friction materials and from the results obtained, it was concluded that the developed composite brake pad had much better mechanical properties than the commercial brake pad. Higher content of grounded coconut powder showed a lower braking impact, comprehensive strength, and hardness. Aigbodion *et al.* (2010) also in an effort to find a replacement for asbestos also developed an asbestos-free brake pad using a bio-waste material, bagasses. The bagasses used in the study were sieved into mesh sizes of 100, 150, 250, 350, and 710 μm . The sieved bagasse powder was used to produce brake pad containing of 70% bagasse–30% resin using compression molding machine. The result showed that samples containing 100 μm (70% bagasse–30% resin) gave favorable properties than other brake pad samples which were tested. It was observed that the lower the sieve sizes of bagasse, the better the properties. The results obtained for the 100 μm sieve size, commercially available asbestos-based brake pad and optimum formulation laboratory palm kernel-based pad by Ibhadode and Dagwa (2008) are all in agreement. Ruzaidi *et al.* (2011) studied the morphology and wear properties of brake pad with the view of replacing asbestos with palm ash and polychlorinated biphenyl (PCB) waste mixed together with metal filler and thermosetting resin binder. Five different ratios were examined and the test results showed that the higher the composition of the palm ash, the better wear, and mechanical properties.

In this study, rubber scrap (tire peels) was used as reinforced material instead of asbestos with other constituents in the production of brake lining. Effect of manufacturing parameters on the tribological and physical properties of the formulated brake lining using Taguchi method will be investigated.

Materials and Methods

Materials

The four materials used for the production of brake lining are reinforced material (rubber scrap – tire peels), friction modifier (graphite), binder (phenolic resin), and abrasive (aluminum oxide).

Method

Material preparation

- The rubber scrap (tire peels) used as reinforced material used in this study was sourced from Altimax RT General Automobile Tire (DOT 650F 3T3). It was cut into pieces and washed thoroughly to get rid of dirt which may have possibly combined with the rubber tire powder. The tire pieces was dried in the sun for 1 week and grounded into fine powder using a bench grinding machine (DT 200A, 550 W). The powder was sieved using a sieve size $\leq 100 \mu\text{m}$ to eliminate any fibers that may be present (Ikpambese *et al.*, 2016; Aigbodion *et al.*, 2010).
- Graphite used in this study as friction modifier used was obtained from used 1.5 V dry cell batteries (TIGER HEAD BRAND). The graphite rod was extracted from the used batteries and crushed to smaller sizes using a hammer. It was then pounded using a mortar and pestle and sieved using sieves size $\leq 100 \mu\text{m}$.
- The phenolic resin used as binder in this study was phenol formaldehyde. It was prepared in the Biochemistry laboratory of Federal University of Technology, Minna, using the procedures outlined by Seong Jin Kim *et al.* (2003).
- The aluminum oxide (CAT. NO. 34143; LOT. NO. 44100) used as abrasive for this study was purchased from a chemical store in Kaduna, Nigeria.

Brake lining formulation

The formulation of brake lining sample consists of a series of operations including mixing, cold and hot pressing, cooling, post-curing, and finishing. In the production of the friction lining, the weights of the rubber powder, phenol-formaldehyde resin, friction modifier (graphite), and abrasive (aluminum oxide) was based on 176 g weight of commercial brake pad (Ikpambese *et al.*, 2016). Hence, the following percentage by weight of rubber powder (45), phenolic resin (30), graphite (15), and aluminum oxide (10) were used for the development of brake lining material. Phenolic resin was poured into a container, followed by the addition of small quantity of sulphuric acid (catalyst) and mixed thoroughly. The required quantity of rubber, aluminum oxide and graphite powders were poured into a separate container and mixed thoroughly manually. The mixture was poured into the container holding the resin and further stirred thoroughly to obtain homogeneous mixture. The mixtures were then placed in a mold of size $116 \times 116 \times 10 \text{ mm}$. The compression and curing of the composite samples was carried at the Polymer Workshop of Nigeria Institute of Leather Research and Science Technology, Samaru, Zaria. A compression molding machine (model; 3851-0, CARVER) was used for the compression of each composite sample. The experimental set up was based on design of experiment (DOE) via Taguchi method and three production parameters namely: molding temperature, pressure, and curing time were considered for experimentation. Hence, there were three input parameters and for each parameters, three levels were assumed as shown on Table 1. For a three-factor-three-level experiment, Taguchi had specified $L_9 (3^3)$ orthogonal array for experimentation as shown on Table 2.

Evaluation of Formulated Brake Lining Properties

Impact strength

The impact test was carried out using a Charpy impact testing machine (Norwood instrument, model No.: 412-07-0715269C) with each test sample produced to the size $80 \times 15 \times 5.5 \text{ mm}$ dimensions, 450 notch of 1.5 mm depth, and 0.20 mm root radius machined from different composition. The impact energy of the testing machine ranges from 0 to 25 J with a pendulum striking at a speed of 2.887 m s^{-1} . The testing method involved fixing each test samples on the anvil of the testing machine and then setting the pendulum at a certain height. The pendulum is then released to impact the specimen at the opposite end of the notch in order to produce a fractured surface. The absorbed energy which produced the fractured surfaces for all the test samples were recorded. The impact strength can be calculated using the eq. [1]:

$$\text{Impact strength } (S_i) = \frac{\text{Absorbed energy } (E)}{\text{Thickness of specimen } (t)} \quad [1]$$

Hardness

The hardness test was conducted using a Shore A hardness tester (Durometer) with each samples prepared to size $60 \times 15 \times 5.5 \text{ mm}$. According to ASTM D2240 standard, three prepared specimens from the same sample of different composition were subjected to applied pressure by a calibrated spring to a spherical indenter and an indicating device which measures the depth of indentation.

Tensile strength

The tensile strength test was performed using Tensometer (MONSANTO; Serial No. 05232). The Tensometer consist of two metal fixtures which clamp the test samples prepared to the size $90 \times 16 \times 5.5 \text{ mm}$. The test specimens were prepared and labeled in compliance with ASTM D638 dumbbell parameters. Specimens dimension was measured using a Vernier caliper of accuracy 0.01 mm. With the machine reading set at 0.00 N, the test was performed by clamping each prepared specimen from different

Table 1 Manufacturing parameters and their levels

Factor	Unit	Level 1	Level 2	Level 3
Molding pressure (MP)	MPa	0.6	0.7	0.8
Molding temperature (MT)	°C	130	150	170
Curing time (CT)	Minutes	8.0	10.0	12.0

Table 2 Experimental design layout using Taguchi orthogonal array L₉ (3³)

S. No.	MP (MPa)	MT (°C)	CT (min)
1	1	1	1
2	1	2	2
3	1	3	3
4	2	1	2
5	2	2	3
6	2	3	1
7	3	1	3
8	3	2	1
9	3	3	2

composition between two metal fixtures. A male punch was then forced into a hole in the fixture thereby causing it to shear along the edge of the hole. The Tensometer was used to push the punch until failure occurs. The tensile strength was determined using the relationship in eq. [2]:

$$\text{Tensile strength } (\delta) = \frac{\text{Max force } (P_{\max})}{\text{Area of sheared edge } (A)} \quad [2]$$

Corrosion rate

Concentrated sulphuric acid was used and mixed with distilled water in the ratio of 3 ml/0.5 ml acid to water. Before immersion in the corrosion medium, the weight and dimension of each specimen taken from the different composition was measured using a Vernier calliper and electronic scale of accuracy 0.01 and recorded. Each specimen were cleansed using distilled water and dry cloth and then immersed into the corrosion medium for 72 h with routine removal of specimens for analysis after every 24 h. During the routine removal, the samples were carefully cleaned and weighed before inserting them back into the corrosion medium and the weight loss was noted (Bashar *et al.*, 2012). The corrosion rate (C_r) was calculated using eq. [3]:

$$\text{Corrosion rate } (C_r) = \frac{k \times \Delta w}{\rho \times A \times t} \quad [3]$$

where $k = \text{constant} = 87.6 \text{ (mm year}^{-1}\text{)}$, $w = 1 \text{ g (1000 mg)}^{-1}$, $A = \text{surface area} = 2[(l \times b) + (l \times t) + (b \times t)] \text{ (mm}^2\text{)}$, $l = \text{length}$, $b = \text{width}$, $t = \text{thickness}$, and $\rho = \text{density}$.

Oil and water absorption

A specimen of $90 \times 16 \times 5.5 \text{ mm}$ dimension was prepared from each samples of formulated composite brake lining material. Each sample was dried in an oven to constant weight. The initial weight of each specimen was recorded using a digital weighing balance. The specimens were then immersed in distilled water and brake fluid (oil), respectively, at room temperature for a period of 3 days. After every 24 h, specimens were taken out and the surface water and oil wiped off with a cloth and weighed. The new weight of each sample during the routine removal was recorded. The weighing was done within 30 s in order to avoid any error that may occur as a result of evaporation. The weight change in oil and water were calculated by subtracting initial weight from the new weight after 72 h of soak. The percentage water or oil absorption by weight after 24 h was determined using eqs. [4] and [5]:

$$\text{Percentage water } (\% W_a) = \frac{\Delta w}{w_1} \times 100 \quad [4]$$

$$\text{Percentage oil } (\% O_a) = \frac{\Delta w}{w_1} \times 100 \quad [5]$$

where $\Delta w = \text{change in weight}$ and $w_1 = \text{initial weight of specimen}$.

Co-efficient of friction

The coefficients of friction of samples were determined using an inclined plane (NORWOOD Instrument Ltd., model No. 14678) of angular calibration which can read between 0° and 45°. The weights used during the test vary from 0.1 to 60 N; while the weight of the specimen attached to the steel plate was determined using a spring balance. These different weight sizes were attached with the aid of an adhesive (STICKO, super glue, model No. COCNO011421). The samples were cleaned of any surface dirt using a dry cloth and then attached to a mild steel plate with the aid of an adhesive. The weight of each test sample attached to the steel plate was measured using a spring balance. With the addition of known weights to the test sample which was placed on the smooth surface of the incline plane set at 0°. The incline plane was operated by raising the plane surface from the horizontal position toward the vertical position through various angles. The process was immediately stopped when the sample began to slide down the plane surface and the angle at that particular point recorded. The coefficient of friction was obtained by calculating the tangent of the angle at which the test sample started to slide down the smooth surface of the plane (Fono-Tamo and Koya, 2013). Load of various weights were placed on each sample and the experiment repeated. The average angles at various loads for the nine samples were then calculated and the corresponding coefficient of friction obtained. The coefficient of friction was evaluated using eq. [6]:

$$\mu = \tan \theta \quad [6]$$

where, μ is the coefficient of friction and θ is the sliding angle in degree.

Wear rate

The wear rate test was conducted using the method reported by other researchers (Bashar *et al.*, 2012; Aigbodion *et al.*, 2010). The dimension of each specimen was measured using caliper of an accuracy of 0.01 cm. The test was conducted by placing each sample clamped in a rigid position along the disk of the grinding machine (model: MASTER bench grinder, MD-250; 220 V – 50 Hz of diameter 250 mm, and speed of 2950 rpm for a period of 5 s). The weights of the samples before and after the grinding were recorded. The difference in the weight from each sample was calculated as the loss in weight. The same procedure was repeated for a period of 10, 20, 30, 40, and 50 s for each sample. The wear rate was calculated using the following relation in eq. [7]:

$$\text{Wear rate } (W_r) = \frac{\text{Weight loss } (\Delta w)}{\text{Sliding distance } (S)} = \frac{\Delta w}{S} (\text{g m}^{-1}) \quad [7]$$

where weight loss (Δw) = weight difference before and after the grinding (g), sliding distance (S) = $2\pi D N t$ (m), N = speed of grinding engine (rpm), D = disk diameter (m), t = time of exposure of each sample to grinding machine (s).

Determination of thermal behavior of formulated brake lining

The thermal behavior of formulated brake lining was studied using thermogravimetric analysis. Sample of brake lining for this analysis was prepared with optimal manufacturing parameters for wear rate. The analysis took place under nitrogen environment at a flow rate of 20 ml min⁻¹ and pressure of 2.5 bars using PerkinElmer TGA4000 model.

Experimental Results and Data Analysis

The results for all the properties of formulated brake lining are shown on Table 3 for the nine samples. The significant effect of the manufacturing parameters on each property is shown using analysis of variance (ANOVA) method, while the optimized values of the manufacturing parameters for the properties of the brake lining formulated are shown using the main effect plots in Table 4. In determining the optimized values for the manufacturing parameters signal to noise ratio (S/N ratio) become viable means to achieve that. The S/N ratio has three categories of quality characteristics which includes; larger-the-better, nominal-the-better, and smaller-the-better. Therefore, the S/N ratios for each property (output variable or response) were determined using Minitab 16 software. Therefore, the optimum level of the process parameters is the level which has the highest S/N ratio shown on the main effect plot. The confidence level specified for all the analysis is 95%.

ANOVA

The ANOVA results obtained for all the variables investigated show how each of the manufacturing parameter affect the output variables. For instant, hardness value show that, molding pressure (77.93%) has the most significant effect on the hardness value, while melting temperature (2.99%) has the least significant effect. The influence of manufacturing parameters on impact strength show that curing time (50.43%) has the most influence on the impact strength follow by molding pressure (39.05%) as shown in Table 5.

Molding pressure has the most significant effect on the tensile strength of the brake lining material with 75.97% and this is followed by curing time with 10.41% significant effect. The corrosion rate of the brake lining formulated is influenced by curing time (71.56%) and melting temperature (19.21%) as shown in [Table 6](#).

The ANOVA result for oil absorption show that molding pressure (63.28%) has the most significant effect on the oil absorption, followed by molding temperature (23.62%). While curing time (40.88%) has the most significant effect on the water absorption property of the formulated brake lining as shown in [Table 7](#).

It was observed that molding pressure (61.46%) has the greatest effect on the wear rate of the formulated brake lining followed by melting temperature (15.76%). While the result obtained for co-efficient of friction as shown in [Table 8](#), indicate that molding pressure (90.11%) has the most significant effect on the coefficient of friction, follow by melting temperature (7.62%).

Signal-to-Noise Ratio

In order to obtain the optimal value of the manufacturing parameters for different variables, the three categories of quality characteristics of S/N ratio must be applied correctly. Hence, the larger-the-better will be applied for the hardness value as expressed in eqn [8]:

$$S/N \text{ ratio} = -10 \log \frac{1}{n} \left(\sum_{i=1}^n 1/y_i^2 \right) \quad [8]$$

where γ =responses for the given factor level combination, n =number of responses in the factor level combination. It is observed from the main effect plot using the S/N ratio of hardness values that the optimal manufacturing parameters are molding pressure: 0.8 MPa (level 3), melting temperature: 170 °C (level), and curing time: 8 min (level 1) as shown in Fig. 1.

And for the impact strength, the optimal manufacturing parameters are molding pressure: 0.8 MPa (level 3), melting temperature: 150 °C (level 2), and curing time: 12 min (level 3) using S/N ratio, the larger-the-better quality characteristics. Similarly, the S/N ratio, the larger-the-better quality characteristics was used to obtain the optimized values of the manufacturing parameters for the tensile strength. Fig. 2 shows the optimized values of the manufacturing parameters at molding pressure: 0.6 MPa (level 1), melting temperature: 150 °C (level 2), and curing time: 10 min (level 2).

In the same vein, the optimal values of the manufacturing parameters for corrosion rate are at molding pressure: 0.8 MPa (level 3), melting temperature: 170 °C (level 3), and curing time: 12 min (level 3) using the smaller-the-better S/N ratio quality characteristic as depicted in eqn [9]:

$$\eta = -10 \log \left(\frac{1}{n} \sum_{i=1}^n y_i^2 \right) \quad [9]$$

where η is the S/N ratio for the lower-the-better case, y_i is the measured quality characteristic for the i th repetition, and n is the number of repetitions in a trial.

The optimization values for the oil absorption using the smaller-the-better quality characteristics for the S/N ratio quality characteristics have been determined. The optimal values are: molding pressure: 0.6 MPa (level 1), melting temperature: 130 °C (level 1), and curing time 10 min (level 2) as shown in Fig. 3.

The optimized values obtained for co-efficient of friction are molding pressure: 0.6 MPa (level 1), melting temperature: 130 °C (level 1), and curing time: 10 min (level 2) using the larger-the-better quality characteristics for the S/N ratio quality characteristic. While wear rate as depicted in Fig. 4 show the optimized values at molding pressure: 0.8 MPa (level 3), melting temperature: 150 °C (level 2), and curing time: 12 min (level 3) using the smaller-the-better quality characteristics for the S/N ratio quality characteristic.

Fig. 1 Main effect plots for hardness.

Fig. 2 Main effect plots for tensile strength.

Thermal Behavior of Formulated Brake Lining

The thermal degradation profile of the formulated brake lining is presented in [Fig. 5](#). The sample degraded between 149.89 and 478.36 °C, with a peak degradation at temperature 394.8 °C. This suggest that the formulated brake lining may be used for a system whose braking temperature does not exceed 300 °C.

Fig. 3 Main effect plots for S/N ratio for oil absorption.

Fig. 4 Main effect plots for wear rate.

Confirmation Test

Regression equations were obtained for all the responses using MINTAB 16 software. The optimized values were used to obtain the experimental values for each of the variable investigated. The same optimized values were used to calculate for each variable.

Fig. 5 Thermal behavior of formulated brake lining.

Table 9 Validation test percentage error

Variable	Calculated value	Experimental value	Percentage error (%)
Impact strength	0.93	0.95	2.11
Hardness	77.57	76.85	0.9
Tensile strength	0.82	0.81	1.22
Corrosion rate	4.31	4.29	0.46
Oil absorption	3.93	3.701	5.83
Water absorption	1.22	1.28	4.69
Co-efficient of friction	0.63	0.64	1.56
Wear rate	2.11	1.98	6.16

Table 9 show the comparison of the two values. For each of the variable, the appropriate regression equations used are as follows:

$$\text{Impact strength } (I_s) = 0.062 + 0.605\text{MP} - 0.00111\text{MT} + 0.0557\text{CT} \quad [10]$$

$$\text{Hardness } (H) = -24.5 + 114\text{MP} + 0.119\text{MT} - 1.17\text{CT} \quad [11]$$

$$\text{Tensile strength } (\sigma) = 98.6 - 93.4\text{MP} + 0.0051\text{MT} + 1.51\text{CT} \quad [12]$$

$$\text{Corrosion rate } (C_r) = 20.9 - 4.70\text{MP} - 0.0468\text{MT} - 0.406\text{CT} \quad [13]$$

$$\text{Oil absorption } (O_a) = -3.62 + 8.00\text{MP} + 0.0220\text{MT} - 0.055\text{CT} \quad [14]$$

$$\text{Water absorption } (W_a) = 1.27 + 2.03\text{MP} - 0.0194\text{MT} + 0.203\text{CT} \quad [15]$$

$$\text{Coefficient of friction } (\mu) = 1.06 - 0.533\text{MP} - 0.000750\text{MT} - 0.00083\text{CT} \quad [16]$$

$$\text{Wear rate, } W_r \text{ (mg m}^{-1}\text{)} = 9.01 - 5.47\text{MP} - 0.0141\text{MT} - 0.0342\text{CT} \quad [17]$$

where MP is molding pressure, MT is melting temperature, and CT is curing time.

Conclusions

The study presented Taguchi method as a reliable method of determining the optimal manufacturing parameters for the improved properties of formulated brake lining using rubber scrap as reinforced material. ANOVA shows that the molding pressure (77.93%) has the most significant effect on the hardness value, while melting temperature (2.99%) has the least significant effect. While the influence of manufacturing parameters on impact strength show that curing time (50.43%) has the most significant influence on the impact strength follow by molding pressure (39.05%). It was observed that the molding pressure: 0.8 MPa

(level 3), melting temperature: 150 °C (level 2), curing time: 12 min (level 3) and molding pressure: 0.6 MPa (level 1), melting temperature: 130 °C (level 1), curing time: 10 min (level 2) are the optimal manufacturing parameters respectively for wear rate and co-efficient of friction. The sample formulated from the wear rate optimal manufacturing parameter degraded between 149.9 and 478.4 °C, with a peak degradation at temperature at 394.8 °C. The confirmation tests obtained for all properties investigated shows a close agreement with the calculated results.

Introduction

Stakeholder consultation is becoming an important component of all policy – and decision – support processes. Dialogue or exchange with stakeholders is a very enriching experience, as it allows scientists or researchers to get exposed to different views, approaches, and expectations on project results. It also enables them to collect feedback and suggestions from a variety of individuals having complementary skills and backgrounds. The involvement of key stakeholders is very useful to get an alternative perspective, which stimulates the scientists or researchers to shift the focus from project activities to intended outcomes in the early stage and to clearly communicate main ideas about the project in terms of objectives, milestones and outputs. However, the involvement of stakeholders with different (and sometimes opposite) views, backgrounds and expectations might increase confusion. Also, dealing with a large number of stakeholders might be an overwhelming exercise and challenges the organisers' capacity.

The present paper addresses these issues so as to share good practices with interested stakeholders and help the policy-makers to achieve concrete and action-oriented results in a more effective way. The methodology was applied within the framework of the POLIMP – Mobilizing and transferring knowledge on post-2012 climate policy implications project (POLIMP is funded by the European Commission under the 7th Framework Programme – Grant Agreement No 603847) and is analytically presented in the following paragraphs.

The remaining paper is structured as follows: Section “Rationale” presents the basic elements of stakeholder engagement process, as well as the levels of POLIMP stakeholders' participation, while Section “Methodological Notes” illustrates the main methodological steps implemented during POLIMP – from the composition and categorisation of stakeholders to dissemination of results – so as to establish an efficient stakeholder engagement. Section “Lessons Learnt” presents the lessons learnt during the POLIMP stakeholder engagement process, as well as the dissemination and communications strategy that was followed, in order to attract more stakeholders to participate actively in POLIMP activities. Finally, Section “Conclusions” summarizes the main points of the paper and provides some concluding remarks.

Rationale

A stakeholder is defined as a person or a group who has a stake or special interest in an issue, policy, or company (Welp *et al.*, 2006). A science-based stakeholder dialogue is defined as a structured communicative process of linking scientists with selected actors who have specialised knowledge and insights that are particularly relevant for the scientific process. In this respect stakeholders are identified based on the relevance of knowledge or certain competencies rather than on the representation of the full spectrum of interests (Welp *et al.*, 2006). This paper addresses both concepts of stakeholders, those with a special interest in climate policy and those in possession of specialised knowledge or competencies, who may be called experts.

Stakeholder engagement is a critical success factor of the POLIMP project (Karakosta *et al.*, 2014, 2015). To engage POLIMP stakeholders sets out two specific objectives:

- 1) To mobilise the collected and processed information to stakeholders, and define suitable formats to that effect; and
- 2) To encourage stakeholders to provide inputs for policy implications and recommendations for the EU and create maximum impacts of these outputs.

First, POLIMP provides stakeholders, such as policy makers, business, NGOs and citizens with a novel and effective opportunity to identify the information needs on the future courses of climate change policy making and their impacts on stakeholders' decisions (Karakosta and Flamos, 2016). It ensures that at different policy- and decision-making levels within the EU, decisions are taken on the basis of the best available knowledge including an increased understanding of opportunities for business and society. Based on

Table 1 Levels of stakeholders' participation

<i>Levels of stakeholders' participation</i>	
Inform	To provide stakeholders with balanced and objective information to assist them in understanding the problem, alternatives, opportunities and/or solutions (e.g., Final Conference, Webinars, Policy Briefs, Climate Change Monitor, Briefing Notes, Climate Policy Database)
Consult	To obtain stakeholders' feedback on policy-makers on analysis, alternatives and/or decisions (e.g., Dialogue, Stakeholder Workshops)
Involve	To work directly with stakeholders throughout the policy-making process to ensure that stakeholder concerns and aspirations are consistently understood and considered in the process (e.g., Dialogue, Stakeholder Workshops, Policy Briefs, Webinars, Expert Response Survey)

the best available knowledge collected and processed on a range of prioritised topics for the current climate policy developments, POLIMP could enhance the insights of policy – and decision-makers on possible courses of climate policy making. This would reduce the uncertainty of policy makers and sector – and company-level decision makers and help them better understand the consequences of different policies and regulatory frameworks on economic sectors and the European society as a whole. Moreover, POLIMP provides stakeholders with ample opportunities to share their experiences and lessons learned with a view to providing targeted input to policy implications and recommendations for the EU and delivering these outputs to a wider range of stakeholders.

Stakeholders can be invited to different levels of participation, depending on the specific purpose that is to be reached: Inform; Consult; and Involve. An overview of the three different levels of stakeholders' participation is given in [Table 1](#).

Below each level of participation is further explained.

a) *Inform*

Dialogue with stakeholders can be purely *informative*: limited in communicating POLIMP results, not requiring further *involvement* of external participants in the research process or seeking to develop a full participatory process ([Dede et al., 2015](#)). In order to raise awareness, POLIMP aims to inform climate policy-makers, researchers and wider stakeholders about the activities and outcomes of the project. All the interested actors continuously benefit from a series of dissemination activities, which aimed to keep them informed for a number of issues concerning POLIMP according to their special nature and interest. The goal is to provide policy-makers and stakeholders with policy implications and recommendations, and to create high impacts, as well as visibility at EU and member state levels.

b) *Consult-Involve*

In the case of full participation, stakeholders may collaborate with POLIMP members, participate in events and provide feedback with a view to contributing in the finalisation of outcomes. The aim of POLIMP is not only to inform policy makers and public, but also to consult, involve and collaborate with stakeholders in order to address knowledge gaps, and further acquire, process and accumulate knowledge for policy debate.

Methodological Notes

In order to establish an efficient stakeholder engagement, it is crucial to:

- Prioritise the main topics/issues that deserve discussion with stakeholders;
- Set the desired outcomes;
- Clarify the right point in time when stakeholders need to be mobilised in order to be more effective and, when needed, maximise the chances of getting valuable inputs;
- Develop a communication strategy, including follow-up;
- Identify the main communication channels for discussing and exchanging ideas with them.

Bearing these points in mind, the purpose of the stakeholders engagement plan is to engage targeted stakeholder groups in POLIMP activities throughout the implementation period and beyond ([POLIMP, 2013, 2016a](#)). A stakeholder engagement process initially contains the identification of suitable stakeholders and relevant information provision ([African Development Bank, 2001; Krywkow and Hare, 2008](#)). The methodological framework, presented in the stakeholder engagement plan, consists of a series of concurrent and consecutive steps to involve stakeholders throughout the process.

Step 1: Composition and categorisation of stakeholders

The element of active involvement in the process of policy– or decision–making constitutes the core characteristic of a stakeholder engagement approach. The composition of a group of stakeholders varies depending on the topic addressed and the group can be comprised by citizens, experts, government members, industry representatives or stakeholders of any kind with an interest in a specific topic ([McTaggart, 1997; Pedrosa and Guimarães Pereira, 2006; Slocum, 2003; Weaver and Cousins, 2004](#)). POLIMP in effect focuses on all those in politics and business who make climate policy-relevant decisions and may have a potential interest in research outcomes addressing knowledge gaps. It recognises a broad sense of stakeholders including both active participants in climate policy (e.g., private or public, regional, national or international organisations/institutions, national ministries, industrial or trade

Table 2 Stakeholder groups

<i>Knowledge functions</i>	<i>Activities</i>	<i>Examples of entities</i>
Knowledge providers	Research-oriented (e.g., desk work, laboratory, field work)	International organisations/institutions (UNFCCC secretariat, OECD/IEA); Joint Research Centre (JRC); national and non-governmental research institutes; business; NGOs
Knowledge users/ implementers	Decision- and implementation-oriented (e.g., management, administration, lobbying/advocacy)	EU institutions (Commission, Parliament, Council, the European Economic and Social Committee, the Committee of the Regions); EU member states (including ministries and political parties); local and regional governments; business sector representatives (trade associations); NGOs; UNFCCC parties (primarily for UNFCCC side-events)
Communicators	Intermediary and catalysing (e.g., networking, mass-mailing)	Media, umbrella organisations in business or NGOs

organisations, NGOs and individual experts) and concerned citizens. For the POLIMP project, its stakeholder engagement activities mainly target the former, a smaller and more specific constituency, while its dissemination and communication activities target the latter, a bigger and broader audience. Between the two are intermediaries and catalysts (e.g., umbrella organisations in business or NGOs), which belong to the former group, but also have leverage and multiplier effects on the latter group.

POLIMP categorises the three stakeholders groups in relation to knowledge function (Table 2).

Regarding the first category, 'knowledge producers', a set of questions remain open, for example:

- What sort of information do we expect from them?
- What incentives do the policy-makers provide?
- What would be their contribution to the results?
- What formal or informal status will they have in relation to the POLIMP project?

These questions are constantly addressed during the designing phase of stakeholder activities, in order to improve the quality of their feedback and to meet expectations from invited stakeholders.

The second category, 'knowledge users', is the main target audience for the processed knowledge, given their capacity as decision makers in policy and business. Questions similar to what are addressed to 'knowledge providers' include:

- What sort of knowledge or information are in demand, and when?
- What incentives do the policy-makers provide?
- What formal or informal status will they have in relation to the POLIMP project?

These categories are function-based, and therefore not mutually exclusive. As indicated above, there might be some overlap between entities identified with respective categories; e.g., umbrella organisations in business or NGOs) provide both the second and third functions (users and communicators). In such a case, the POLIMP researchers would regard entities with multiplier effects as 'knowledge users'.

For POLIMP the stakeholder engagement plan concentrates on the first two categories, 'knowledge providers' and 'knowledge users'. Provided that a dissemination and communication plan would address media to reach out concerned public, the stakeholder engagement plan does not address 'communicators' further on.

Derived from knowledge providers as well as knowledge users, stakeholders were differentiated by region and by sector. This leads to the categorisation of the following three European regions:

- *Western and Northern Europe*, with a proactive attitude and strong capacity to deal with mitigation and adaptation of climate change.
- *Southern Europe* affected by recent financial and economic crisis for which climate policy is currently not a major priority.
- *Central and Eastern Europe* in the transformation from an energy-intensive economy and possibly also affected by the financial and economic crisis for which climate policy is politically challenging and could be undesirable.

Across Europe and inside each Member State, POLIMP recognises the following sectors as climate-relevant:

- Energy production and distribution,
- Energy-intensive industry (e.g., iron & steel, cement, chemical, metal, paper & pulp, glass, lime),
- Mining (hard coal, minerals),
- Other ETS sectors (e.g., aviation),
- Transport (e.g., automobile, rail, shipping),
- Energy end-use (e.g., lighting and heating in buildings, appliances),
- Land-use (e.g., forestry, agriculture, real estate),
- Finance and trading (e.g., private investment banks and funds, pension funds, market traders).

It was assumed to be unlikely that POLIMP project would have a comprehensive coverage of all the above sectors. On the contrary, the consortium would target at, for example, the three most relevant sectors for the selected topic to maximise the impacts. The final selection of the sectors depends on the final choice of the topic and location for a thematic workshop.

Step 2: Stakeholders selection

Next, stakeholders were screened and selected in order to form a database of potential participants in consultation as well as knowledge dissemination. The stakeholders selection process focuses on not only parties to the UNFCCC (e.g., negotiators and policy makers in developed, developing countries and at the EU level), as well as all other non-party actors (e.g., NGOs, academic and corporate sectors both in developed and developing countries, media and the public), who are engaged in UNFCCC negotiations, but also those active in EU-domestic policy processes (e.g., climate change, energy, transport).

The first stakeholder screening was made on the basis of inputs from all project partners about the stakeholders within their home countries and contact networks that, they consider, may be interested in the outputs of the POLIMP project or may provide inputs to POLIMP through stakeholder meetings and workshops. The shortlist of important stakeholders was compiled from this input, including 173 stakeholders from 24 EU countries and from EU institutions (as of July 2013) with countries in Western, Southern and Central/Eastern Europe represented, although with relatively few representatives from Southern countries. The list has been updated with more stakeholders that have been identified in the context of the country preparatory dialogues and through other contact persons of each POLIMP partner on demand. This initial screening provides a good starting point for organising the country preparatory dialogues and for identifying further stakeholders once the topics of the stakeholder workshops are defined. It covers stakeholders from the first two knowledge-based categories as defined earlier in this article.

Potential sources for the identification of stakeholders associated with the relevant member states and topics are the following:

- Outcome of the first screening;
- Preliminary inputs from partners who are responsible to host meetings;
- Inputs from the report on stakeholders mapping;
- Inputs from the report on gap analysis;
- Contributions from stakeholders.

As key ‘knowledge providers’, a limited number of key stakeholders could contribute to the process from early on, especially at the stage of completion of gap analysis across regions/countries or topics. At the beginning of POLIMP, stakeholders were asked to identify priority issues of climate policy in need of additional or new knowledge. The risk is that each stakeholder may have different views about where and to what extent knowledge gap exists. This risk can be reduced by early briefing about the objective, process and expected results of the project.

Step 3: Modes of stakeholder consultation

The POLIMP project has developed a methodology for stakeholder consultation involving physical meetings and online platforms (Fujiwara *et al.*, 2015b). The POLIMP project designed different modes (Table 3) of stakeholder consultation (e.g., workshops, dialogue, events, web-tools) for different objectives (POLIMP, 2015, 2016a, b).

While the project partners hosting events generally have agreed on the basic framework summarised below in each category, it is up to them to select and decide on the specific designs that would suit them best and have maximum impacts.

Step 4: Preparatory dialogues

Preparatory dialogue is one of the main consultation tools to reach out to key stakeholders (e.g., policy-makers, businesses, researchers and NGOs) in EU member states (Fujiwara *et al.*, 2015a). Because bi-directional stakeholder participation is desired, the POLIMP consortium listened to their opinions, and gathered their feedback.

POLIMP initially envisaged to establish a clear link between dialogue and the workshop, calling the dialogue as preparatory to the meeting. It was expected to lay a ground before entering into discussion at the workshop, to have common understanding and perception about the policy framework, policy objectives, or policy instruments. It was expected that dialogue participants could further influence other stakeholders through their own connections (cf. ‘entities with multiplier effects’). Hosting organisations agreed on the basic framework in the stakeholders engagement plan including the timing and targeted countries, examples of different patterns to conduct dialogue and a guideline to structure the dialogue process. Further detail about the format and modality of dialogue can be made flexible and tailored to interests, priorities or needs of regions and countries hosting dialogue. In principle participation in dialogue are limited on an invitation only.

Table 3 Modes of consultation

<i>Modes of consultation</i>	<i>Location</i>	<i>Objectives</i>	<i>Main target groups</i>
Workshops	BE, UK, DE	Presentation of knowledge gaps; preparation for recommendations	Knowledge producers and users
Dialogue	NL, AU, PL, GR	Identification of knowledge gaps	Knowledge producers and users
UN-Side events	PL, Peru, FR	Presentation of research outcome	Stakeholders registered at UNFCCC
Web-Tools	n.a.	Sustainable and long-term engagement	All stakeholders

The ETS dialogue has been implemented throughout the period October 2013–March 2015. By the end of March 2015, more than 70 stakeholders from five countries (Greece, Poland, Austria, Hungary and the Netherlands) in total have participated in the dialogue processes. (The process was organised by four POLIMP partner organisations (University of Piraeus Research Centre (UPRC), Instytut Badan Strukturalnych, (IBS), University of Graz and JIN Climate and Sustainability) and coordinated by the Centre for European Policy Studies (CEPS).) Each dialogue organiser selected the topics corresponding to the most immediate stakeholder workshop, but allowed some variation in its interpretation of topical questions depending on the national circumstances or priorities, and developed its own method in accordance with the basic framework that is common to all dialogue processes. The POLIMP research team aimed at an iterative process of stakeholder consultation through a series of interviews or/and group discussions that enable the stakeholders to make contributions. The example of a methodology adopted in Greece is presented below.

Example of Preparatory Dialogues in Greece

For preparatory dialogue the University of Piraeus Research Centre (UPRC) in Greece held two sets of interviews a questionnaire with follow-up interviews. The first round focused on the role of carbon markets mechanisms in climate negotiations (market mechanisms, renewables, Article 9 Renewable Energy Directive), targeting 19 experts from academia, research institutes, the business-private sector, the public sector and NGOs. Questions concerned carbon markets, the Clean Development Mechanism (CDM) and the EU ETS, inter alia (Karakosta *et al.*, 2011, 2010). The second round focused on the ETS, consulting 12 stakeholders in Greece from academia as well as from research institutes and businesses in the energy sector. Questions focused on the assessment of economic impacts on the cost-effectiveness of the EU ETS, increasing harmonisation in the implementation of the EU ETS, and national stakeholders' views on how the 2030 framework will influence the political support for the EU ETS.

Several steps were taken for the dialogue process. Input elicitation began with the identification of key stakeholders for participation, followed by a personal invitation that was sent to the identified stakeholders. After receiving a positive answer, UPRC conducted interviews with them based on a questionnaire developed for this purpose. Preparatory material was subsequently developed in the form of a questionnaire, in order to be completed individually by stakeholders and also to facilitate discussion during interviews. Stakeholders were then invited to participate in the procedure and their interest was confirmed. Self-filling in of questionnaires and conduction of interviews took place in parallel.

Then UPRC analysed their feedback and identified the key outcomes. Feedback analysis provided preliminary results that were presented to selected stakeholders during thematic workshops conducted within the framework POLIMP (see step 5). Results of dialogue were reported in a common template used by hosting organisations. The template include basic sections in order to present key concepts and related policy questions in need of preparatory discussions, the main discussion points on which participants agreed or disagreed, as well as the key findings. The process of the dialogue preparation and implementation was completed in consecutive steps, as diagrammed in the Fig. 1 below.

Step 5: Thematic workshops

Thematic workshops, aim at engaging stakeholders in consultation with researchers from the early stage. This approach enables stakeholders to provide researchers with early feedback to preliminary analysis on knowledge gaps and to help them further develop evidence-based policy recommendations. The main target groups of these workshops were knowledge providers and users. In principle participation in the workshops was limited to invitation only. A list of invited participants consists of EU and member states policy-makers, industry and business representatives, researchers from academia and think-tanks, representatives of NGOs and other stakeholder groups.

The size of workshops varied, largely depending on the timing and topics to be discussed. For selecting invited participants, organisers took account the geographic and sector groupings that are most relevant to the chosen topic on the one hand, and representation of knowledge providers (mainly technical experts and researchers) and knowledge users (mainly policy makers and market participants) on the other hand. On the average, 20–30 stakeholders are expected to participate in a full day workshop. Within POLIMP duration, four Stakeholder Workshop were implemented, enabling stakeholders to provide researchers with early feedback to preliminary analysis on knowledge gaps and to help them further develop evidence-based policy recommendations.

Fig. 1 UPRC dialogue process.

Scheduling the 'preparatory' dialogue at national or regional levels prior to the workshop in major capitals such as Brussels and London would better inform EU and national policymakers and stakeholders. Some of the dialogue participants could directly present to or share their experiences with stakeholders from other countries or the EU policy circle.

The hosting organisation ensures that discussion with stakeholders should be well-structured and evidence-based, presentation be short and concise and comments be kept even shorter (Karakosta and Fruhmenn, 2014). The purpose of this approach is to leave sufficient time for stakeholders to have clear understanding, exchange ideas and contribute to findings and, eventually, recommendations. The workshop programme consisted of several sessions moderated by session chairs and introduced by short presentations and interventions. For the ETS workshop, one session focused on the design issues in the context of the ETS reform debate and another on the implementation issues particularly relevant to groups of countries characterised by weak economic performances or other national circumstances, Central and Eastern Europe and Southern Europe.

In order to structure discussions for the thematic workshop on the EU ETS, key findings and messages of dialogue outcome were communicated in a background paper to speakers. This required focusing on topical policy issues related to the background research to be undertaken by the POLIMP team and expanded for discussion with external speakers and stakeholder participants. Prior to each workshop, a draft Policy Brief or a background paper was circulated. After the workshop, this draft Policy Brief or a background paper was finalised, incorporating feedback from stakeholders and preliminary suggestions for policy implications and recommendations. Three Policy Briefs were published after three workshops and circulated to a broader group of interested citizens beyond the workshop participants. Such feedback includes preliminary suggestions for policy implications and recommendations to policymakers (Fujiwara and Hofman, 2016; Fujiwara *et al.*, 2015b; Hofman and Van der Gaast, 2014; Michaelowa and Tuerk, 2014). In each Policy Brief, messages and recommendations are supported by the key outcomes of the project and tailored to policy- and decision-makers' priority issues.

Step 6: Dissemination of results

Based on a Dissemination and Communication Plan, POLIMP consortium members collected information targeted on priority issues in need of additional or new knowledge, and processed the information into integrated packages for decision makers. The processed information is presented in various formats, which are considered to be user-friendly and accessible, to reach target groups and a wider public. The tools for spreading excellence, exploiting results and disseminating knowledge are the following:

Targeted materials

- Policy-oriented publication series (e.g., Policy Briefs, Working Documents laying a sound basis on which policy options can be formulated, detailing methodologies, tools or indicators and presenting empirical data, Climate Change Monitor reports which focus on development in the UNFCCC negotiations as well as the EU climate change policy, and Briefing Notes which contain general conclusions from the knowledge collection and procession work, regarding policy implications).
- Collaboration with relevant European Initiatives.
- POLIMP Climate Policy Database, an ontology for annotating and structuring the knowledge related to climate policies.
- POLIMP Webinars Series, where stakeholders were actively engaged, enriching with their experience the discussion on climate policy.
- Bilateral contact (email and in person) with targeted audience for the provision of feedback.
- POLIMP Expert Response Survey Series, which engaged a targeted group of stakeholders and experts on matters relating to EU and international climate and energy policy.
- POLIMP Climate Policy Database, that allows stakeholders to explore, edit and extend the concentrated knowledge.
- Providing access to POLIMP data for stakeholders closely involved.
- Acknowledging stakeholders in all deliverables & POLIMP results where they provide feedback.

Workshops and events

- Presentations into events, dialogues and press conferences, as well as interventions/announcements at international conferences/forums/events of on-going initiatives in the same area etc.
- POLIMP final conference. In those events climate policy and other experts provided input on the results of POLIMP.

Distribution of promotional materials

- Production and distribution of promotional material e.g., brochure, flyer/leaflet, etc. The promotional material informs the wider audience about POLIMP goals and objectives and directed interested parties to sources of more detailed information.

Scientific publications

Articles to engage academia and researchers promoting the research conducted.

E-activities

- POLIMP website presenting the POLIMP results and containing useful dissemination material.
- POLIMP online knowledge platform "Climate Policy Info Hub", exploring impacts and implications of international and EU climate policy for decision-makers in policy, business and civil society and supporting informed science-based EU climate policy-making.
- POLIMP Climate Change Monitor Series focus on development in the UNFCCC negotiations, as well as the EU climate change policy and provides a regular stream of most updated information in a concise form.

Fig. 2 Different dissemination means for different needs.

- POLIMP Briefing Notes containing general conclusions from the knowledge collection and procession work, regarding policy implications: socioeconomic aspects, technology transfer, land use, market mechanisms and other policy options.
- Web-based tools (e.g., QA forms-through which questions and comments were send during the webinars).
- Newsletters, Press Releases, Videos.
- Announcements & discussions in social media and EC platforms.

The pyramid dissemination structure finally reached policy makers and related stakeholders by producing policy briefs (Fig. 2).

Lessons Learnt

Stakeholders Engagement

The POLIMP project identified three main lessons learned from stakeholders' engagement activities. Sharing lessons from a methodological perspective, POLIMP could help policymakers improve the process for EU climate policy-making and invite researchers to future EU-funded projects, especially those aimed at coordinating and supporting action.

First, the portfolio approach based on combination of different modes of stakeholder consultation to fit for different purposes and for different target groups enabled the POLIMP team to have an extensive coverage of regions/countries as well as sectors. It is significant that most of the consortium members were involved in more than one consultation process. Consequently, POLIMP succeeded in reaching out stakeholders in the EU, three European regions (Western, Central and Eastern, and Southern Europe), seven countries (Poland, Greece, Austria, Hungary, the Netherlands, UK and Germany) as well as international negotiators and observers of climate policy.

It was assumed that the team would target at the most relevant sectors for the selected topic to maximise the impacts. Reflecting on the original focus of POLIMP and the composition of the its team, most of the stakeholders invited to the POLIMP consultation process were based on climate change mitigation policy: sectoral orientation towards 'energy production and distribution', 'energy-intensive industry (e.g., iron & steel, cement, chemical, metal, paper & pulp, glass, lime)', and to a less extent 'Finance and trading (e.g., investors and market traders)'. The format of regional or national dialogue allowed the team to complement the above sectoral coverage with those sectors that are of strategic importance to the targeted countries (e.g., mining in Poland and shipping in Greece).

Second, while it is crucial to narrow down the focus of interview questions and workshop sessions to facilitate interaction between policymakers and stakeholders, it was difficult to identify the topics and sub-topics in advance. Although the work plan developed a methodology on how to determine the topics in a systematic way, policy issues tend to be time-sensitive. More specifically, there was time lag between selection of the topics and discussion of the topics, and between the discussion in preparatory dialogue and the discussion in a stakeholder workshop. In effect timely transition from physical meetings (preparatory dialogue and stakeholder workshops in M6-29 (October 2013 – September 2015)) to online consultation (surveys and webinars in M27-36 (July 2015 – April 2016)) ensured that the topics selected earlier (e.g., financing renewable energy and the ETS reform) would remain on the table throughout the POLIMP period.

Third, among other modes of consultation, preparatory dialogue turned out to be methodologically effective but at the same time particularly challenging for implementation. There were practical issues related to planning and implementation at regional/national levels: e.g., selection of topics, contacts with stakeholders, scheduling meetings or interviews. Although it was envisaged to

hold preparatory dialogue before the first stakeholder workshop, in effect the process started after the first workshop (April 2015) and lasted longer until the third workshop (February 2015). Thus, real feed-in from regional/national levels to the European level was realised at the third workshop.

Another challenge to dialogue implementation was the need to coordinate a largely decentralised approach. In the preparation stage, although the coordinator circulated the guidelines for dialogue (see Annex 1 of D2.2) specified indicative elements (with optional ones), it was left to the hosting organisation to decide the format of dialogue. Even though the guidelines also suggested likely steps to implement the dialogue process, this required a series of bilateral briefing and interaction (Q&A), in some cases bilateral elaboration on designing the questionnaire. In the implementation stage, it was difficult to have an overview of progress being made at regional/national levels, particularly to support the hosting organisation in reaching out stakeholders at the minimum level that is required in each country for analytical purposes. In the analysis stage, diverse circumstances and interests across countries and sectors, which was the case for the EU ETS dialogue, made it impossible to summarise or draw common messages.

These three lessons, the portfolio approach, selection of policy-relevant topics, and a decentralised approach, are related and complementary to each other. Sharing these lessons and exchanging experiences from the POLIMP project with ongoing and future EU projects (e.g., CARISMA for the former) would contribute to maximising the impacts beyond the end of the project.

Dissemination and Communication

Within the POLIMP duration, and more particular during the implementation of POLIMP dissemination strategy several challenges were faced and addressed. The main challenges are presented in this document.

To begin with, one of the main POLIMP objectives was to achieve the vast communication and dissemination of the POLIMP achievements, but also their sustainability, ensuring the dissemination to the wider possible range of stakeholders groups. The main challenge to the effective, efficient and tailor-made diffusion of POLIMP message was the selection of the appropriate means and ways to address the communication of each POLIMP activity, knowledge produced and publication to the targeted stakeholder group. The process started with the appropriate selection of the information and experience from a wide range of research findings and activity results shared in POLIMP. The promotion and further facilitation of knowledge exchange on key policy issues was initially challenging and finally was elaborated through a target-oriented Dissemination and Communication Plan. By finalising and updating the POLIMP communication and dissemination strategy, the project team made it sure that the appropriate measures are used for the efficient and effective information transfer while the desirable message is shared among the appropriate audiences.

In order to meet the needs of different stakeholder groups, the POLIMP team developed and presented a series of publications with specific guidelines, in order to reach targeted group of stakeholders and experts on matters relating to EU and international climate and energy policy, as well as to present the methods used towards the outreach of the POLIMP results and progress. POLIMP publications contain general conclusions from the knowledge collection and procession work implemented during POLIMP, regarding policy implications: socioeconomic aspects, market mechanisms and other policy options.

Another challenge to the POLIMP team was creating the maximum impacts of the findings. Within the POLIMP duration information and data were collected to identify where knowledge gaps exist, provide insights and raise awareness on the implications of possible directions of international climate policies and a future climate policy regime. In order to ensure and increase the POLIMP visibility, a variety of targeted events, stakeholder consultation workshops and side events were implemented, communicating POLIMP progress and outcomes and engaging the stakeholder target groups in an ongoing direct consultation process. Thus, many stakeholders showed interest to cooperate with POLIMP and actively participate in its events and provide their feedback on the activities and progress of POLIMP.

The third challenge was the level of expectation from stakeholder engagement. Although an important number of experts were attracted to participate to POLIMP events, some of them were not further committed to providing feedback on policy implications and recommendations or exchanging knowledge and experience on the topics of discussions and outcomes of the events. In addition, despite the constant efforts of the POLIMP team to engage into POLIMP network a wide range of different stakeholders by presenting POLIMP activities and disseminating informational material, many policy makers, experts and stakeholders were not willing to participate to POLIMP activities, although their work was associated with climate and energy policy issues and with POLIMP objectives in general.

For a success factor, through the POLIMP dissemination and communication plan, the association between objectives, targets and message to disseminate has been thoroughly considered. The entire communication and dissemination strategy was based on a solid foundation comprised by clarity, transparency and honesty in order to support information availability and open access. All the stakeholders and policy makers were continuous recipients of a series of dissemination activities, which aim to keep them informed for a number of issues concerning POLIMP progress, concept and activities, through awareness raising, knowledge sharing, interest creation, mobilization and various other activities.

Future climate policy initiatives, both at an EU and at a global level are encouraged to follow the POLIMP dissemination plan, which contains tailor-made communication activities aiming at target groups with specific objectives and direct messages, and to implement the effective policies and practices that were proved to be particularly successful during the POLIMP

dissemination efforts. It remains challenging to further address the recognized aforementioned issues, regarding the wide variety of source information and key conclusions, target groups, types of events, and the effective and constant stakeholder engagement.

Conclusions

POLIMP identified key lessons learned from stakeholder engagement and the respective dissemination activities. The POLIMP team managed to have an extensive coverage of regions/countries as well as sectors, following a portfolio approach based on combination of different modes of stakeholder consultation to fit for different purposes and for different target groups. In addition, the format of regional or national dialogue allowed the team to complement the sectoral coverage with those sectors that are of strategic importance to the targeted countries. Thus, among other modes of consultation, preparatory dialogue turned out to be methodologically effective but at the same time particularly challenging for implementation. There were practical issues related to planning and implementation at regional/national levels concerning the overall portfolio approach, the selection of policy relevant topics and the need to coordinate a largely decentralised approach. However, as the ETS publication process highlighted, a decentralised approach was suitable in topics with wide difference and diversity of interests among stakeholders. This is less clear in case of RES publication which was presumably based on literature review.

The dissemination and communication strategy developed to mobilise stakeholders engagement thoroughly considered the association between objectives, targets and message to be disseminated. Tailor made communication activities were successful in supporting knowledge sharing concerning POLIMP progress, concept and activities. However, important issues emerged regarding the dissemination and communication strategy, particularly the wide variety of source information, key conclusions, target groups, types of events, in addition to the need of effective and constant stakeholder engagement. Finally, exchanging knowledge and experience acquired through POLIMP could support ongoing and future EU projects on achieving concrete and action-oriented results in a more effective way.

Introduction

The emissions from cars can have a deadly consequence on human life, as seen with the CO emission, which has been proven to be fatal to human life in a confined space. In addition, research has shown that exposure to fuel emissions can have a carcinogenic effect on humans. This is a huge concern for people as the number of vehicles hitting the road increases globally. Car manufacturers and drivers can help reduce these harmful emissions in three separate ways: increasing engine efficiency, increasing vehicle efficiency and finally; standardized driving technique, unobstructed traffic conditions, cruising at an optimum speed for the vehicle and the reduction of cold starts which is the research interest in this paper. [Fig. 1](#) points out the world approaches in reducing transport emissions, where the green area is the paper's interest.

Models for emissions and fuel consumption factor estimations can be broadly divided into two categories: Average Speed Model and Instantaneous Emission Model.

Average Speed Model

The average speed approach is commonly used to estimate emissions from road traffic. This approach is based on aggregated emission data for various driving patterns. Driving patterns are represented by their mean speeds alone ([Wielenmann et al., 2005](#)). The average speed, vehicle class, size and year are used to obtain a derived speed emission function. This function fails to consider that using different cycles (i.e., with different driving behaviours and vehicle dynamics) with the same average speed will obtain different emissions and fuel consumption factors ([Myung et al., 2004](#)). This approach is limited to regional and national estimates ([Wielenmann et al., 2005](#)).

The MODEM project, in an attempt to overcome the average speed model limitations, established a set of 14 realistic driving cycles from a set of on-street measurement exercises ([Pang and Brace, 2004](#)). Emission data for the 14 cycles were then obtained from a range of vehicles using chassis dynamometer tests. A set of charts relating the emissions CO, HC, NOx and CO₂ and fuel consumption to second by second speeds for the driving cycles were then produced.

[Ryu et al. \(2015\)](#) have proposed and developed a corrected average emission model. This is an improved average speed model that accurately calculates CO₂ emissions on the road. When emissions from the central roads of a city are calculated, the existing average speed model only reflects the driving behaviour of a vehicle that accelerates and decelerates due to signals and traffic. Their results showed that the average speed model underestimated CO₂ emissions with an increase in acceleration and idle time for a speed range of 20 km/h and below, which is the speed range for traffic congestion. Based on these results, they

Fig. 1 Emission reduction approaches.

analysed the relationship between average emissions and instantaneous emissions according to the average speed per link unit, and they developed a model that performed better with improved accuracy of calculated CO₂ emissions for 20 km/h and below.

Instantaneous Emissions Model

The use of instantaneous emission models was introduced to overcome the limitations of the average speed model. This model measures emissions continuously at the exhaust during chassis dynamometer tests and stores the data at a particular time interval (typically 1 s) (Wielenmann *et al.*, 2005). An averaged emission value is assigned to every pair of instantaneous speed and acceleration values (measured simultaneously). The emission function can then be defined as a two-dimensional matrix of speed and a product of speed and acceleration. This modal method still has limitations in estimating transient, high acceleration emissions since these matrices are derived solely from chassis dynamometer tests (Myung *et al.*, 2004). Mera *et al.* (2019) have reported that in real-world driving, most Euro 5 and 6 diesel passenger cars exceed the nitrogen oxides (NOx) emission limits of type approval procedure. The emission factors of the fleet of Euro 6 vehicles show high variability, irrespective of the NOx control technology. It was concluded that high instantaneous NOx emissions represent a large number of total NOx emissions, although they are produced in a small percentage of driving time. A theoretical constraint of these high NOx emissions could reduce emission factors by 30%–82%. The emission of high instantaneous NOx emission is related to characteristic speed modes of urban, rural and motorway sections, and is primarily produced in a narrow engine speed range of approximately 700 rpm. In general, the probability of producing high instantaneous NOx emission increases as the engine speed, the exhaust gas temperature or the vehicle speed is increased.

Comparison of Vehicle Emissions Measurement Technique

Regulatory testing includes a pre-scale vehicle certification testing as the manufacturer should prove their vehicles to be under emissions standards (type approval tests) which are being carried out on chassis dynamometer emissions test equipment. Another procedure is in-service inspection and maintenance. This procedure is an idle test used without a load applied to the engine where a gas analyser probe is inserted into the tailpipe to measure the concentration of vehicle emissions (Vehicle & Operator Services Agency (VOSA), 2006). Sometimes, a load can be applied to the engine for more representative measurements (Wenzel *et al.*, 2000), but that can lead to excessive costs (Wenzel, 2003). Present, built-in, on-board diagnostic (OBD) systems can identify faulty parts in a car (Baltusis, 2004). In terms of on-road emission monitoring, there are two types of emission tests as below.

Monitoring Equipment

This method is used to measure the emission concentrations in ambient air (Fuller, 2006), this type uses a pump to sample the ambient air and sometimes samples of PM or HC emissions collected and analysed in a laboratory (Harrison *et al.*, 2003). This type of technology is considered to be good in measuring the in-use vehicle fleet rather than single vehicles measurements (Fuller, 2006). One of their applications is in Tunnel studies, where this equipment is placed inside the tunnel in order to measure the emissions factors for CO, CO₂, NOx, and HC (Hausberger *et al.*, 2003).

On-Road Remote Sensing

This method involves some tools set up on a roadside to measure the emissions from a single car when it passes (Achour, 2012). These tools have been developed by researchers for a better understanding of emission factors CO, NO, HC and PM (Bishop and Stedman, 1996; Jimenez *et al.*, 1999; Moosmuller *et al.*, 2003). On-road remote sensing was successfully used in many regions to specify vehicle fleet emissions (Bishop *et al.*, 1997; Bradley *et al.*, 2000; Stephens *et al.*, 1997). Fuel consumption has been improved for emissions factors using this technique (Pokharel *et al.*, 2002). However, there is no direct method to determine the details of the mode of operation such as gear, engine speed, etc., at the moment of measurement (Wenzel *et al.*, 2000).

Results from regulatory measurements methods are not sufficient. Chassis dynamometer testing must be carried out (North, 2006) and can be carried out in parallel by either instantaneous or modal emissions with the aggregate bag measurements required for certification (Sturm *et al.*, 1998). Using drive cycles in chassis dynamometer testing is not always representative of real drive cycles (Samuel *et al.*, 2002; Färnlund and Engström, 2001; Esteves-Booth *et al.*, 2001). Its usage covers only a limited area of driving modes (Younglove *et al.*, 2005). As a result of this, much research has been carried out in developing realistic driving cycles. Comparing these drive cycles showed differences in the measured emissions (De Haan and Keller, 2001; André, 2004). Since using the on-board emission monitoring for measuring instantaneous emissions makes data acquisition relatively quick, cost-effective and allows the drive cycles as well as emission factors to be evaluated (Rakha and Ahn, 2004; Ensfield, 2002; Hart *et al.*, 2002; Davis *et al.*, 2005). A correlation between measured and estimated emissions was found to be within 5% for CO₂ and NOx (Kihara *et al.*, 2000) and within

10% for HC and CO (Frey *et al.*, 2001). Much research has been conducted using emission analysers in order to calculate instantaneous emissions. For example, Ayala *et al.* identified the different hydrocarbon species emitted from the tailpipe (Ayala *et al.*, 2002).

As it was mentioned previously that vehicle emission estimation conducted on a single car requires validation by using measuring equipment fitted to the car under test (Cadle *et al.*, 2004, 2003). One of the parameters has been found to affect emissions levels is driver behaviour (Holmen and Niemeier, 1998; Nam *et al.*, 2003). Traffic jams have also been studied as one of the parameters that affect emission levels (Daham *et al.*, 2005; Unal *et al.*, 2004). Bishop *et al.* (2019) have mentioned that data from portable emissions measurement systems (PEMS) and other sources have allowed the discrepancy between type approval and real-world fuel economy and nitrogen oxides (NOx) emissions to be both identified and quantified. However, a gap in the knowledge persists because identifying this discrepancy does not allow us to predict real-world fuel economy and emissions accurately.

Comparison of Vehicle Emissions Modeling Technique

Many modeling methods have been developed in estimating the emission factors in the transport sector (Latham *et al.*, 2000; Düring *et al.*, 2005). National emissions inventories in areas (such as a country or a state) are important to assess the emissions levels, identify the air quality and help reduce the hazardous emissions affecting human health and environment.

Studies have been done in developing these modeling methods to estimate the emission factors CO, CO₂, HC, NOx and PM (Latham *et al.*, 2000). This study also investigated other factors such as evaporative emissions and PM emissions of brake dust (Düring *et al.*, 2005). The standard method in Europe and US is the average-speed models. The most useful data set for the work carried out for Europe is COPERT (Computer Programme to estimate Emissions from Road Transport) (Ntziachristos and Samaras, 2000) or the TRL (Transport Research Laboratory) emissions factors. Both can describe emissions in terms of grams per kilometre travelled [g/km] and are functions of vehicle speed (Edward and Bright, 2008), such that for the TRL factors:

$$EF_{i, m, n} = k + ax + bx^2 + cx^3 + \frac{d}{x} + \frac{e}{x^2} + \frac{f}{x^3}$$

where a, b, c, d, e, f and k are coefficients specific to a given engine size, m and technology level, n, x is the average vehicle speed in kilometres per hour (g/km) EF_{i, m, n} is the emissions value, in grams per kilometre travelled (g/km) for a given species i, of age m and engine size, n.

Emissions calculations exist for each of carbon dioxide (CO₂), carbon monoxide (CO), particulate matter (PM), oxides of nitrogen (NOx) and unburned hydrocarbons (HC) (Ekström *et al.*, 2004). COPERT4.V9 has recently been made available (Düring *et al.*, 2005). Validation studies for COPERT as well as method comparison studies are still on-going. Ekstrom *et al.* found an agreement in NOx emissions between COPERT and on-road sensing measurements, while a weaker agreement was noticed for CO and HC (COPERT was overestimated) (Ekström *et al.*, 2004). Another programme MOBILE6 has been compared with on-road sensing measurements. Noticeable differences have been found between the two methods (Pokharel *et al.*, 2002). Smit *et al.* presented a new modeling approach for dealing with road traffic emissions: VERSIT+. When compared to COPERT, higher accuracy was noticed with VERSIT+ with respect to emission estimations (Smit *et al.*, 2007).

Although average-speed models have world-wide use in the transport sector, there are some difficulties facing this method. Difficulties include fleet test data, fleet activity patterns, acceleration issues and identifying of local emissions (Wenzel *et al.*, 2000). However, good correlations between the predicted results of the modeling packages and the actual data obtained by direct measurement are still maintained.

Achour *et al.* have utilized COPERT and the combination of On-board diagnostic data extraction incorporated in all modern passenger cars. COPERT emission factors have been employed to allow for the real-world vehicular activity in order to better estimate the contribution of private cars to local emissions inventories (Achour *et al.*, 2011). A built-in data acquisition package has been developed in LabVIEW to log and save the data extracted from the OBD system. This data is then analysed to obtain driving cycles of specified routes which have been plotted so that emission factors could be obtained, Fig. 2 (Achour *et al.*, 2011).

Advantages of this method are: easy to follow, inexpensive and the results are in a good fit to the estimated values. Achour *et al.* also used the gas analyser, which measures resultant emissions directly from the exhaust manifold for the validation of the results for Dublin City, Ireland, Fig. 3. Good correlations between the predicted results of the modeling packages and the actual data that is obtained by direct measurement are still maintained (Ekström *et al.*, 2004). The same method has been employed in Aleppo city, Syria to establish a representative tool for the local authority in identifying the air quality caused by traffic emissions (Achour *et al.*, 2012).

Discussion and Conclusion

With respect to controlling air pollution, specifically from transport, there is a need to establish a method quickly and effectively to estimate on-road vehicle emissions. There are many methods to measure harmful emissions that are being produced by vehicles into the earth's atmosphere. However, with few methods that have been presented and discussed in this paper, it is now possible to monitor a range of engine signals such as drive cycles, emissions and fuel consumption in real time. Some data can be visualized

Fig. 2 Flow chart of development of driving cycle. Reproduced from Achour, H., Carton, J.G., Olabi, A.G., 2011. Estimating vehicle emissions from road transport, case study: Dublin city. *Applied Energy* 88 (5), 1957–1964.

Fig. 3 Dublin driving cycle (DDC). Reproduced from Achour, H., Carton, J.G., Olabi, A.G., 2011. Estimating vehicle emissions from road transport, case study: Dublin city. *Applied Energy* 88 (5), 1957–1964.

via a PC attached with the tools in the form of graphed data plots. The results pertained from such packages estimate these plots in real time using OBD signals. The use of computer software reduces the need for bulky expensive analysis equipment and provides quick and accurate emissions estimates of the European regulated emissions (CO, HC, NO_x and particulate matter). The main two advantages of these methods are: user-friendly and can be used anywhere using portable equipment that can fit easily in the back seats of the car without affecting driver's behaviour or opposing people's life to any danger.

In conclusion, as each country has a unique driving cycle which represents the characteristics of the driving and the real amount of emissions from vehicles, individual testing is necessary for each region. An overall review of the most common emission modeling techniques is presented in this study with the purpose of being considered by future researchers as a primarily database in vehicle emission modeling techniques for further work in this field.

Small to Medium Burners for Agricultural Pellets

Dalibor Petković, University of Niš, Pedagogical Faculty in Vranje, Partizanska, Vranje, Serbia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Energy services could be greatly improved by use of agricultural biomass in small-scale combustion units. Wood pellets are a reliable and proven fuel to be used in small-scale combustion units. However, these units should preferably be able to use different types of biomass depending what it is locally available. Therefore, studies have been focused on exploring the suitability of using agricultural residues for small-scale heat and power generation using direct combustion. Steam-treated pellets can help to address technical barriers that limit the uptake of pellets as a fuel for electricity generation, but there is limited understanding of the cost and environmental impacts of their production and use.

A modified Hartmann dust explosion tube was employed to determine the Minimum Explosible Concentration (MEC) and the flame speed for three Pakistani agricultural wastes: bagasse, rice husk and wheat straw (Saeed *et al.*, 2015) where it was shown the lean limits for these pulverized agricultural waste biomasses were comparable to that of pulverized wood but were much leaner than those for coal and hydrocarbon fuels, which indicate that these biomasses are highly reactive. In study (Cardozo *et al.*, 2014) was compared the combustion of different agricultural residues in a single unit designed for wood pellets. In study (McKechnie *et al.*, 2016) was investigated life cycle environmental (greenhouse gas (GHG) and air pollutant emissions) and financial implications of electricity generation from steam-treated pellets, including fuel cycle activities (biomass supply, pellet production, and combustion) and retrofit infrastructure to enable 100% pellet firing at a generating station that previously used coal. Impacts of retrofit infrastructure become increasingly significant at lower generating station capacity factors, further favoring steam-treated pellets for both environmental and financial metrics (McKechnie *et al.*, 2016). In study, (Nilsson *et al.*, 2011) the costs and energy requirements for the production of pellets from agricultural raw materials were analyzed. The energy use in manufacturing pellets from air-dried crops was generally no higher than when moist sawdust was used as the raw material. The objective of work (Carvalho *et al.*, 2013) was to evaluate the technical and environmental performance of a 15 kW pellet boiler when operated with different pelletized biomass fuels, namely straw (*Triticum aestivum*), *Miscanthus* (*Miscanthus* _ giganteus), maize (*Zea mays*), wheat bran, vineyard pruning (from *Vitis vinifera*), hay, *Sorghum* (*Sorghum bicolor*) and wood (from *Picea abies*) with 5% rye flour. The investigation in the international market shows that mixed biomass pellets are promising fuels and with the appropriate support these fuels have many prospects for the future (Karkania *et al.*, 2012). The use of biomass pellets would not only create new market opportunities for agricultural industries, it would also reduce dependence on coal, as well as the greenhouse gas emissions associated with coal use (Karkania *et al.*, 2012). In paper (Tauro *et al.*, 2018) was examined the potential for biomass pellets to become a sizable low-carbon, renewable energy source that could compete with and substitute fossil fuels in specific economic sectors in Mexico where it was estimated that the market energy potential for pellets from currently available agricultural and forest residues in Mexico is between 131 and 233 PJ/yr, with total costs ranging from 6.3 to 12.8 USD/GJ. In paper (Dai *et al.*, 2015), a ceramic foam burner with embedded alumina pellets was designed, which set different shapes of tubes by taking can advantage of the discrete pellets. An experimental system was built to study the effects of the pellet diameter and pellet location on the combustion of low-concentration coal mine methane (LCM) (Dai *et al.*, 2015). Results indicates that the heat transfer features of 13-mm pellets are more similar to those of 10-PPI ceramic foam compared with 6-mm pellets and 9-mm pellets (Dai *et al.*, 2015). The combustion performance in a double-layer burner packed with alumina pellets of different diameters was experimentally studied in article (Gao *et al.*, 2012). In study (Qu and Feng, 2015), methane/air combustion in a two-zone catalytic alumina pileup-pellets burner with equivalence ratios varying from 0.55 to 0.70 was researched.

Conventional small to medium burners for agricultural pellets can be used for combustion of agricultural pellets. Main problem is low ash melting temperature for biomass from agriculture. After the burner finish combustion as it cool down ash is transformed from liquid to solid state and layer of ash block the wholes on grate for provision of air in combustion chamber. In this article was presented and conventional small to medium burners for agricultural pellets.

Materials and Methods

Biomass Waste Management

According to the European Union standardization there are six procedures in the biomass waste treatment process:

1. Eco-design,
2. Biomass waste decreasing,
3. Biomass waste reusing,
4. Recycling and making compost,
5. Energy from biomass waste,
6. Biomass waste disposing.

In order to optimize the system for biomass waste management based on decreasing of pollution of life environment and for the cheapest solution there is goal to develop the biomass waste management process. This innovative solution could lead to revolution in the biomass waste issue. By entering of the main data for biomass waste, quantity and composition for the some region, the client could know which is the best solution for the biomass waste treatment and transport for the region. Several biomass waste treatments are included:

- Recycling,
- Combusting,
- Making compost,
- Performing anaerobic digestion, and
- Disposing of biomass waste.

There are several indicators which are calculated according the input data. These indicators are:

- Global warming,
- Heavy metals emission,
- Nitrogen oxide emission,
- Smog formation,
- Water pollution.

Therefore the system has seven modules. These modules

- Calculation of emissions from collection and transport of biomass waste,
- Calculation of emissions from anaerobic digestion,
- Calculation of emissions from combustion,
- Calculation of emissions from recycled waste,
- Calculation of emissions from disposal,
- Calculation of emissions from compost,
- Calculation of cost benefit.

Burner for Agricultural Pellets

Fig. 1 shows the flowchart of the pelletizing process where it was shown the main process steps. Afterwards each pellet boiler has own process flowchart as it shown in Fig. 2.

Conventional small to medium burners for agricultural pellets can be used for combustion of agricultural pellets. Main problem is low ash melting temperature for biomass from agriculture. After the burner finish combustion as it cool down ash is transformed from liquid to solid state and layer of ash block the wholes on grate for provision of air in combustion chamber. In our construction this kind of problems are eliminated and burner is applied with mechanical system for eliminating the ash from grate. Burner of 120 kW have been produced (assembled) and is in operation today (Fig. 3).

Fig. 1 The pelletizing process flowchart.

Fig. 2 Process flowchart of the pellet boiler.

Fig. 3 Pellet burner for agricultural biomass.

Conclusion

The demand for biofuel pellets has increased considerably in recent years, causing shortage of the traditional raw materials sawdust and wood shavings. Use of biomass fuels for electricity generation can simultaneously contribute to a number of common policy objectives, including: increasing the use of renewable energy; reducing greenhouse gas emissions; compliance with air pollutant emissions regulations; and encouraging economic development in communities dependent on agriculture and forestry sectors.

In this article conventional small to medium burners for agricultural pellets was used for combustion of agricultural pellets. Main problem is low ash melting temperature for biomass from agriculture. After the burner finish combustion as it cool down ash

is transformed from liquid to solid state and layer of ash block the wholes on grate for provision of air in combustion chamber. In this article was presented and conventional small to medium burners for agricultural pellets.

Small-scale wood combustion systems have been well developed and reached a high quality and performance level. The energy efficiency has increased, the emissions have decreased, fully automatic operation systems have been developed and the combustion technology has been optimized for woody biomass fuels.

Small to Medium Scale Gasification Plant

Dalibor Petković, University of Niš, Pedagogical Faculty in Vranje, Partizanska, Vranje, Serbia

Introduction

Biomass is going to play an increasing role in the energy supply of the future, as it is an important renewable source of energy and the only source of renewable carbon. The efficient use of biomass is currently receiving increasing attention. Gasification – as an innovative and viable technology for the thermal conversion of biomass – has been the focus of considerable research for a number of decades.

Gasification is recognized as one of the most promising technologies to convert low quality fuels into more valuable ones. The principal problem related with the use of biomass in gasification processes is the high amount of tar released during the pyrolysis step. However, biomass is a low-grade energy fuel and has limited uses as a direct feedstock to produce energy. For this reason the study of innovative thermochemical processes, such as gasification and pyrolysis, to transform the solid biomass into more valuable fuels is of fundamental importance for the success of biomass exploitation. Gasification converts the low-grade solid biomass under high temperature into gaseous fuel called syngas.

A modified Hartmann dust explosion tube was employed to determine the Minimum Explosible Concentration (MEC) and the flame speed for three Pakistani agricultural wastes: bagasse, rice husk and wheat straw (Saeed *et al.*, 2015) where it was shown the lean limits for these pulverized agricultural waste biomasses were comparable to that of pulverized wood but were much leaner than those for coal and hydrocarbon fuels, which indicate that these biomasses are highly reactive. In study (Cardozo *et al.*, 2014) was compared the combustion of different agricultural residues in a single unit designed for wood pellets. In study (McKechnie *et al.*, 2016) was investigated life cycle environmental (greenhouse gas (GHG) and air pollutant emissions) and financial implications of electricity generation from steam-treated pellets, including fuel cycle activities (biomass supply, pellet production, and combustion) and retrofit infrastructure to enable 100% pellet firing at a generating station that previously used coal. Impacts of retrofit infrastructure become increasingly significant at lower generating station capacity factors, further favoring steam-treated pellets for both environmental and financial metrics (McKechnie *et al.*, 2016). In study, (Nilsson *et al.*, 2011) the costs and energy requirements for the production of pellets from agricultural raw materials were analyzed. The energy use in manufacturing pellets from air-dried crops was generally no higher than when moist sawdust was used as the raw material. The objective of work (Carvalho *et al.*, 2013) was to evaluate the technical and environmental performance of a 15 kW pellet boiler when operated with different pelletized biomass fuels, namely straw (*Triticum aestivum*), Miscanthus (*Miscanthus _ giganteus*), maize (*Zea mays*), wheat bran, vineyard pruning (from *Vitis vinifera*), hay, Sorghum (*Sorghum bicolor*) and wood (from *Picea abies*) with 5% rye flour. The investigation in the international market shows that mixed biomass pellets are promising fuels and with the appropriate support these fuels have many prospects for the future (Karkania *et al.*, 2012). The use of biomass pellets would not only create new market opportunities for agricultural industries, it would also reduce dependence on coal, as well as the greenhouse gas emissions associated with coal use (Karkania *et al.*, 2012). In paper (Tauro *et al.*, 2018) was examined the potential for biomass pellets to become a sizable low-carbon, renewable energy source that could compete with and substitute fossil fuels in specific economic sectors in Mexico where it was estimated that the market energy potential for pellets from currently available agricultural and forest residues in Mexico is between 131 and 233 PJ/yr, with total costs ranging from 6.3 to 12.8 USD/GJ. In paper, (Dai *et al.*, 2015) a ceramic foam burner with embedded alumina pellets was designed, which set different shapes of tubes by taking can advantage of the discrete pellets. An experimental system was built to study the effects of the pellet diameter and pellet location on the combustion of low-concentration coal mine methane (LCM) (Dai *et al.*, 2015). Results indicates that the heat transfer features of 13-mm pellets are more similar to those of 10-PPI ceramic foam compared with 6-mm pellets and 9-mm pellets (Dai *et al.*, 2015). The combustion performance in a double-layer burner packed with alumina pellets of different diameters was experimentally studied in article (Gao *et al.*, 2012). In study (Qu and Feng, 2015), methane/air combustion in a two-zone catalytic alumina pile-up-pellets burner with equivalence ratios varying from 0.55 to 0.70 was researched. Torrefied biomass has several benefits, such as higher energy density, good grindability, higher flowability and uniformity (Li *et al.*, 2012). The outlet of a mechanical biological treatment plant for mixed municipal solid waste is further processed to produce RRBf (Refined Renewable Biomass Fuel) within the frame of the EU Lifeþ project MARSS (Material Advanced Recovery Sustainable Systems) (Schulzke *et al.*, 2017). In paper (Dasappa *et al.*, 2004) addresses case studies of a low temperature and a high temperature industrial heat requirement being met using biomass gasification (Dasappa *et al.*, 2004). In paper (Verma *et al.*, 2017) provides a detail review on the need of drying of biomass before co-firing, different technologies used for biomass drying, biomass co-firing to the existing coal fired power plants and the environmental benefits of biomass co-firing. In paper (Perna *et al.*, 2015) conventional and advanced biomass gasification power plants designed for small cogeneration application were defined. A techno-economic feasibility study of liquid bio-fuel production from biomass to meet the demand for public transport in small communities was presented in article (Mustafa *et al.*, 2017).

In this study is presented small gasification plant (downdraft Imbert type). Different biomass fuels have been successfully tested. There is possibility to expand the idea and to use produced syngas for powering the gas motor and produce heat and power in the same time (small cogeneration plant).

Conclusion

The interest on the exploitation of biomass as source of energy has continuously increased in the last decade. Biomass has been recognized as one of the most attractive alternatives to fossil fuel, even if is not yet competitive. Many research efforts have been successfully made to develop efficient and convenient process for biomass exploitation. However, biomass is a low-grade energy fuel and has limited uses as a direct feedstock to produce energy. For this reason the study of innovative thermochemical processes, such as gasification and pyrolysis, to transform the solid biomass into more valuable fuels is of fundamental importance for the success of biomass exploitation.

Sustainable and Environment Friendly Power Sources for Long Duration Environment Monitoring

Jekan Thangavelautham, University of Arizona, AZ, United States

© 2020 Elsevier Inc. All rights reserved.

Introduction

Field sensor networks have many important modern-day applications and have been deployed for environmental monitoring, particularly forest management, wildlife-preservation, air quality, water quality and soil erosion monitoring (Fig. 1; Akyildiz *et al.*, 2002). These devices are also emerging as important tools in disaster prediction, including measuring winds in a hurricane, measuring rising seawater from storm surges, inland flooding, sea-erosion, monitoring spread of forest fires, monitoring avalanches, earthquakes, volcanoes and tsunamis. Field sensor networks play an important role in monitoring critical variables from the environment. They are also feeding complex computer models used to perform advanced prediction and planning.

This has all been made possible thanks to rapid miniaturization of low-cost electronics (particularly micro-computers), sensors, actuators and radios into ever-smaller packages that consume low average power of 5 W or less. An example field sensor network module architecture is shown Fig. 2. The micro-computers are typically combined into a single System on a Chip (SoC) that enables mass-manufacturing and customization. System on a Chip contains all the components of a typical computer including input/output ports, CPU, memory, storage and some peripherals such as Graphics Processing Units (GPUs) and short-range 2.4 Ghz wireless radio (Wi-Fi). Integration of these components onto a single chip, lowers the cost of production making the cost of a micro-computer a few dollars and increases power efficiency. The sensor networks in turn communicate to other nodes via radio. The SoC in turn is connected to a sensor payload that monitors the environment and stores data typically on a solid-state data storage system. The entire system is powered with an onboard power supply that provides power to the SoC which in turns power all the connected peripherals.

To be practical, once deployed, field sensor network modules need to operate unattended, ideally for years. A key to making these sensor systems practical and ready for wide-scale use is the need for high-energy power supplies. Power supplies, including power generation and storage technologies have been slow to advance compared to electronics, sensors, actuators and radios. This is principally due to the limitations with the material used in power supply components.

Photovoltaics and Wind Generators

Photovoltaics are a common power source used to power sensor networks. They are composed of single-junction amorphous silicon or triple-junction Gallium-Arsenide semi-conductor cells. The cells absorb insolation (in the form of photons) and produce electricity. Single junction cell range in efficiency from 5% to 20% while triple junction cells reach 25%–35%.

However, photovoltaic panels are bulky, requiring regular cleaning and need to be actively pointed towards the sun for best results. Plummeting market prices of solar panels from the late 1990s onwards make them one of the leading options for powering environmental sensors. The challenges remain in powering the sensor when sunlight is not available, including during inclement weather and night time. Another alternative is a wind generator. Wind generators consist of a dynamo connected to a wind turbine. The turbine spins producing current which is rectified using power electronics. Although wind-generators contain many moving parts and can be large, they have become attractive due to their low-cost from mass-production. Wind generators are well

Fig. 1 Field sensor networks have ever-growing applications in environmental monitoring. They are playing a critical part in continuous observation of water ways (left), <http://eurogoos.eu/member-product/real-time-data-oceanographic-buoy-vida/> forests (center), <https://blog.adafruit.com/2016/10/25/using-circuits-sensors-to-study-dendrometry-dimensions-of-trees-in-alaska-citizenscience/> and in precision agriculture (right), <http://www.projectwatersense.nl/>.

Fig. 2 A Field sensor network module architecture. Drawn for the encyclopedia article by Jekan Thangavelautham.

sited in certain natural environments such as coastlines, mountain passes and flat plains. Due to their large footprint and need for periodic maintenance, they are only promising for large field applications.

Batteries

Daily variabilities experienced by both photovoltaic systems and wind power generators, mean that these power sources need to be coupled with a battery to store excess capacity and kick-in when there is an input power shortage. Batteries are electro-chemical devices that store electricity in chemical bonds. Current battery technology typically serves as a limiting factor in terms of life and performance of field sensors. This is due to low specific energy of batteries. This is despite the fact that rechargeable batteries have made substantial improvements over the past 30 years in terms of specific energy, overall reliability and power density. 30 years ago several battery technologies were promising including lead-acid, nickel metal hydride, silver-zinc and lithium-ion batteries. Since then lithium ion batteries, particularly containing lithium cobalt oxide (LiCoO_2) or lithium iron phosphate (LiFePO_4) have surpassed these other battery technologies to permit higher specific energy, fast-charge, large number of charge-discharge cycles, long cycle and shelf-life. For the lithium cobalt oxide chemistry, the overall reaction is the following:

However, for long life applications, batteries need to be recharged or replaced often. In some instances, they are ideally coupled with photovoltaics. In other instances, this presents a major challenge in remote environments with limited accessibility. Significant work is being done to address the energy limits of current batteries (Ritchie, 2006; Tarascon and Armand, 2004) but current trends show that batteries cannot meet the high-energy requirements of long-life field sensor networks.

Rechargeable batteries still trail behind non-rechargeable batteries that have higher specific energy and shelf-life. Non-rechargeable batteries can be designed to be the only power source for field sensors, provided the field sensors operate periodically and for low-power. In particular, communication from a remote environment over long distances in the range of kilometres requires direct satellite communication or the cell phone network taking up significant power. Continuous advancement in communication devices are reducing these power demands but still require high-energy power sources.

Batteries can be sized to be larger to make-up for their low-specific energy, but they contain cathode, anode and electrolyte material that do not bio-degrade and are harmful if dispersed into the environment. High-energy batteries such as lithium thionyl chloride (LiSOCl_2) batteries (500–700 Wh/kg) requires even more care in terms of use and disposable as they are highly reactive and susceptible to explosion from shock and vibration. The reaction is given as follows:

Other non-rechargeable batteries such as lithium manganese dioxide (LiMnO_2) have higher specific energy compared to rechargeable batteries at 280 Wh/kg, and are well protected from damage and leaks, but still face the environment disposal problem. Alkaline batteries are common for use in consumer electronics, have excellent shelf-life and competitive specific energy of 200 Wh/kg however they contain chromium in their electrolyte which is a major environmental hazard. Another promising new technology is the lithium-air battery. Lithium air batteries have specific energy of 12,000 Wh/kg and in theory they are rechargeable. These batteries in the laboratory have achieved 50–100 charge/discharge cycles however run into challenges with reliability. The challenges are with the cathode that result in build-up of irreversible Li_2O that translates into steady loss of lithium.

Fuel Cells

An alternative to batteries are fuel cells. Fuel cells are electrochemical energy conversion devices that convert chemical energy directly into electrical energy (Barbir, 2005). Table 1 shows common fuel cell technologies. Unlike a battery, fuel cells must be constantly fed with fuel and oxidizer to produce electricity. There are different fuel cell technologies based on operating temperature, chemistry of electrolyte, fuel and oxidizer used. Some of the fuel cells listed utilize low-cost fuels such as natural gas,

Table 1 Fuel cell technologies

<i>Fuel Cell</i>	<i>Electrolyte</i>	<i>Operating temperature</i>	<i>Electrical efficiency</i>	<i>Fuel oxidant</i>
Alkaline fuel cell –AFC	Potassium hydroxide solution	15–90°C	20%–60%	H ₂ O ₂
Proton exchange membrane fuel cell PEMFC	Proton exchange membrane	15–80°C	40%–70%	H ₂ O ₂ /Air
Direct methanol fuel cell (DMFC)	Proton exchange membrane	15–130°C	20%–40%	CH ₃ OH O ₂ , Air
Phosphoric acid fuel cell PAFC	Phosphoric acid	160–220°C	55%	Natural gas, bio gas, H ₂ , O ₂ , Air
Molten carbonate fuel cell MCFC	Molten mixture of alkali metal carbonates	620–660°C	65%	Natural gas, bio gas, gasoline, H ₂ , O ₂ , Air
Solid oxide fuel cell SOFC	Oxide ion conducting ceramic	800–1000°C	60%–65%	Natural gas, bio gas, gasoline, H ₂ , O ₂ , Air

methanol and gasoline. However, they operate at high temperatures and produce CO₂. This makes them unsuitable for use in pristine environments.

Solid-Oxide and Molten Carbonate fuel cells can utilize a range of fuels including hydrocarbons and hydrogen and are strongly immune to poisoning from impurities such as sulphur. However, they require high operating temperatures, have long start-up times and produce CO₂ when using hydrocarbons.

Alkaline, Polymer Electrolyte Membrane (PEM) and Direct Methanol Fuel Cells (DMFC) all operate at low temperatures. Alkaline fuel cells operate at lower efficiencies and require an electrolyte which requires relatively large containers/casing. However, Alkaline fuel cells are known to be reliable having been used as a power source on several space crafts and on the International Space Station. It is the bulky size and low-operating efficiencies that makes Alkaline fuel cells less attractive for sensor networks.

However, two of the remaining technologies including, PEM fuel cells and direct-methanol fuel cells are both attractive for sensor networks. Both operate at low-temperatures and are quiet.

Overall, PEM fuel cells are mature amongst fuel cell technologies and can operate at cell efficiency as high as 60%–65%. They react with hydrogen and oxygen to produce electricity and water. Their overall reaction is given below:

The storage and release of hydrogen is typically a challenge. However, there are new practical solutions that are simple, that offer high specific-energy and low-temperature solutions. Oxygen is obtained directly from the air or pressurized storage tanks or chemical sources. Air-based PEM fuel cells have reduced power density, but are convenient avoiding bulky, pressurized oxygen tanks.

Direct methanol fuel cells use methanol and oxygen from the air to produce electricity. The overall reaction for the direct methanol fuel cell is given below:

DMFCs tend to have lower efficiencies than PEM, longer start-up times and produce carbon dioxide and water. However, direct methanol fuel cells are attractive, because methanol is relatively easy to produce, store and has higher energy densities than conventional hydrogen storage methods. The main challenge with direct methanol fuel cells is an inherent limitation with the fuel-cell design compared to PEM. Direct methanol fuel cells produce CO₂ as a waste product. This requires an effective ventilation system to prevent build-up of CO₂.

Carbon dioxide can build-up in the fuel cell and dissolve in the water to form carbonic acid (H₂CO₃), a mild source of corrosion and degradation of fuel cell components including the membrane and carbon support layer. A second source is the formation of carbon-monoxide, (CO) an intermediary in the generation of CO₂. Carbon monoxide can poison the platinum catalyst, resulting in irreversible damage to the cell. Together, these sources can cause high rates of unreliability, lower operating efficiencies and, worse reduced performance or poisoning resulting in significant loss of power.

PEM Fuel Cells

PEM fuel cells using hydrogen and oxygen is more attractive compared to the other fuel cell technologies for sensor network applications. However, PEM fuel cells are not widely used in field applications because they face significant hurdles. Firstly, PEM fuel cells are faced with the problem of degradation of their components that result in shortened lives and lower reliability compared to batteries. A second major challenge is the storage of hydrogen. Conventional methods of hydrogen storage are bulky and inefficient, providing only a marginal advantage over current batteries. A third major challenge is that the fuel cell produces lower power compared to batteries. A fourth challenge is that PEM fuel cells have high capital and operating costs. Significant progress is being made in all these areas. Our research addresses the first three challenges.

PEM Fuel Cell Overview

PEM fuel cells became the focus of our interest in high-energy power supplies because it is one of the more mature technologies and shows significant potential for both high-energy and long-life applications (Barbir, 2005). A PEM fuel cell Membrane Electrode Assembly (MEA) has several major components that are all subject to degradation (Fig. 2). They are the Gas Diffusion Layer (GDL), bi-polar plates, the membrane and catalyst layers. The GDL facilitates transfer of input gasses to the anode and cathode. The bi-polar plates have an important role in distributing the reactant gases to the anode and cathode, conduct electrical current within the cell and help to remove heat from the active area, while preventing leakage of gasses. The anode catalyst layer facilitates the oxidation of hydrogen molecules into protons while the membrane allows for the transport of protons from the anode to the cathode. The cathode catalyst layer facilitates the assembly of protons and oxygen molecules into water via a reduction reaction.

Component Degradation

Extensive research has been done to identify the mechanisms that degrade fuel cell components, including the Gas Diffusion Layer (GDL), membrane and catalyst layers. Gas Diffusion Layer (GDL) degradation affects the ability of the cell to absorb reactants. This degradation includes loss of hydrophobicity from corrosion of Polytetrafluoroethylene (PTFE) in the cathode. This can result in flooding causing loss in performance (Kandlikar *et al.*, 2011). Degradation of the GDL can reduce or block gas passageways resulting in choking of the fuel cell. A major source of GDL degradation has been due to mechanical compressions resulting in stress and strains that reduce the micropore regions. This reduces gas transport and thus reduces the effectiveness of the GDL. Freeze thaw cycles are well known to damage the GDL as freezing water expands and damages the micro-pores. Another source of damage to the GDL is corrosion of carbon layers and dissolution of platinum catalyst layers (Barbir, 2005; Wu *et al.*, 2008). However, it should be noted that many of these sources of GDL degradation can be prevented by avoiding such conditions as structural damage, flooding or freezing.

Membranes are also subject to degradation and can be classified into three categories, thermal, mechanical and chemical (Wu *et al.*, 2008). An important source of membrane degradation is due to mechanical stress and strain. The root cause of this degradation is flooding. Membranes once weak are prone to formation of pinholes that result in fuel cross-over and significant reduction in power generated. This is followed by catastrophic failure of the fuel cell (Liu *et al.*, 2001). Mechanical stress and strain is known to occur due primarily to humidity and temperature cycling. Humidity is known to impact the mechanical properties of the membrane. With too high a humidity, the membrane curls up and with too little humidity the membrane hardens and dries out. The impact of relative humidity cycling can be severe. It has been shown that a membrane cycled between a Relative Humidity of 30% and 80% faces structural failure after only 100 cycles (Huang *et al.*, 2006). A second source of membrane degradation is due to chemical attack. The result from chemical attack is reduced strength of the membrane leading to structural failure.

In many cases, platinum catalyst degradation in the cathode is an important factor in fuel cell durability and life (Liu *et al.*, 2001). One cause of catalyst degradation is the dissolution of the platinum particles into ions. The ions either redeposit on large platinum particles or dissolve and migrate away from the catalyst layer and into nearby regions (Kandlikar *et al.*, 2011). Sustained degradation reduces the available catalyst surface in the anode and cathode resulting in loss of power. It also weakens the carbon support structure that holds the platinum and vice-versa through carbon corrosion.

Carbon corrosion is another important source of degradation in a fuel cell. The carbon structure breaks into particles that migrate into the membrane and GDL. The migrating platinum catalyst and carbon particles weakens the membrane structure as discussed above, causing irreversible structural damage ultimately resulting in tears and pinholes. The fuel cell catalyst is impacted by the oxidation of the platinum particles. Oxidation of the platinum particles results in the formation of surface films of platinum oxide that effectively reduces the available catalyst surface area resulting in loss of power. While oxidation of platinum reduces the surface area, it is also known to protect platinum particles beneath the oxide layer from dissolution.

Fuel Cell Life Time Prediction & Degradation

Based on results from several degradation models (Bi and Fuller, 2008; Thangavelautham and Dubowsky, 2013; Darling and Meyers, 2003; Fowler *et al.*, 2002) we produce a combined equation to predict the effect of fuel cell catalyst life. The inputs to the model include voltage V , temperature T , humidity, h and voltage oscillation amplitude, λ . This equation for τ_{clife} in years presumes each operating variable has an independent effect on the life of the fuel cell catalyst. The equation is given below:

$$\tau_{clife} = a_V e^{-k_V V} a_T \cdot e^{-k_T T} \cdot (a_h \ln h + k_h) \cdot (1 - a_\lambda \lambda) \quad (5)$$

The equation considers the effect of operating voltage, operating temperature, operating humidity and voltage oscillations. The list of variables used and their respective values are shown in Table 2.

For field applications, ambient temperature and humidity may change over the course of a day and over the seasons. Next, we model the impact of humidity and temperature oscillations on the life of the fuel cell membrane. A second degradation phenomenon modelled is degradation of the membrane due to humidity cycling given below. Based on the experiments from Huang *et al.* (2006) and others, the PEM fuel cell membrane can only withstand a finite number of humidity cycles that result in

Table 2 Constant value for fuel cell life prediction model

Variable	Value
a_v	3.11×10^{14}
a_T	7.67 years
a_h	-3.37×10^{-1}
a_λ	4.173 V^{-1}
k_h	2.77
k_v	-4.48 V^{-1}
k_t	$-3.75 \times 10^{-2} \text{ C}^{-1}$

Note: Drawn by Thangavelautham, J., Strawser, D., Dubowsky, S., 2017. The design of long-life, high-efficiency PEM fuel cell power supplies for low power sensor networks. International Journal of Hydrogen Energy 42, 20277–20296.

Table 3 Fuel cell catalyst life comparison for field sensor network

Conditions	Predicted fuel cell life
Operating voltage 0.78 V, 0.2 V oscillation, no environment control	0.27 years
Operating voltage 0.78 V, 0.2 V oscillation, 15% humidity, +5°C dew point	2.2 years
Operating voltage 0.78 V, 0.02 V oscillation, 15% humidity, +5°C dew point	12.2 years

Note: Drawn by Thangavelautham, J., Strawser, D., Dubowsky, S., 2017. The design of long-life, high-efficiency PEM fuel cell power supplies for low power sensor networks. International Journal of Hydrogen Energy 42, 20277–20296.

stress loading culminating in mechanical failure of the membrane.

$$\tau_{mlife} = \Delta t_{hosc} \cdot \frac{b_{memb}}{RH_{max} - RH_{min}} \quad (6)$$

where Δt_{hosc} is the humidity cycling period, b_{memb} is a membrane specific constant and is 0.02 for Nafion NR111, RH_{max} and RH_{min} is the maximum and minimum relative humidity.

The total life of the fuel cell is then modelled as the following:

$$\tau_{life} = \min(\tau_{clife}, \tau_{mlife}) \quad (7)$$

where τ_{life} is the expected life of the PEM fuel cell. In summary, the expected life is the minimum of the catalyst life presented earlier and life of the membrane due to humidity cycling. These factors independently impact the fuel cell. Catalyst degradation begins with performance degradation of the catalyst and finally results in catastrophic loss, while membrane degradation results in mechanical damage to the membrane that results in the formation of pinholes and ends up in catastrophic loss.

Using annual temperature and humidity conditions of a location such as Negev, Israel, we can predict the net effect on life of a fuel cell power supply in the field. We presume the fuel cells operating at 0.78 V and voltage oscillations are at 0.2 V. Using ambient temperature and humidity (in other words no environment control) the expected fuel cell life is 0.27 years (Table 3).

Next, we set the fuel cell to operate at 10% humidity and operate the power supply 5 degrees above dew point. The annual maximum and minimum dew point in Negev, Israel. By effectively lowering the operating temperature and humidity, we expect to increase the life of the fuel cell. In addition, lower operating humidity also reduces the chances of flooding. The resultant fuel cell life is 2.2 years (Table 3).

Furthermore, we can reduce voltage oscillations experienced by the fuel cell system to 0.02 V. Our studies show that we can minimize oscillations to 0.02 V further extending life to 12.2 years (Table 3). By effectively controlling the humidity, temperature, operating voltage and voltage oscillations we can extend the operating life of the fuel cell.

Fuel Storage

Another major challenge as noted earlier is hydrogen storage. High pressure and cryogenic storage of hydrogen are clearly impractical for small, low power applications such as sensors networks. A third practical option is the use of chemicals including metal hydrides and hydrocarbons. Conventional reversible metal hydrides release hydrogen through changes in pressure or temperature. Reversible hydrides are valued because of their ability to be recharged with hydrogen, they are not ideal for long-life field applications because they normally have low hydrogen storage densities (defined as the weight of hydrogen divided by the total weight of the hydride) on the order of 1%–2%. However, there exists other higher hydrides with much higher yield but they require much higher temperatures, in the order 200–700°C. Achieving such high temperatures for small, low-power devices limits the potential field applications and increases complexity. An alternate option is the use of chemical hydrides that release hydrogen through chemical reaction (Kong *et al.*, 1999). This include hydrocarbons, but they also contain trace amounts of sulphur that can poison a PEM fuel cell.

Hydrolysis is the reaction of chemical hydride with water to produce hydrogen. However, popular water activated metal hydrides including sodium borohydride (NaBH_4) and magnesium hydride (MgH_2) have low hydrogen content, low-reliability and require expensive catalysts. Alternatives such as calcium hydride do not require catalyst but have low yield. Our research has focused on lithium hydride (LiH) which has higher net hydrogen content by mass than calcium hydride. Hydrogen can be released by exposing lithium hydride to water releasing the hydrogen from the hydride and stripping water of its hydrogen. Lithium hydride unlike other water activated hydrides requires no complex mechanisms or catalysts to start, control and complete the hydrogen release reaction. Our experimental studies show that water activated lithium hydride can achieve 95%–100% reaction completion rates with excess of water (Fig. 4) (Strawser *et al.*, 2014).

Fuel Cell Operations

Power Management

The proposed fuel cell power supply consists of a fuel cell-battery hybrid system (Fig. 3). The fuel cell constantly charges a battery and the battery/fuel cell system periodically powers an electrical load. By having several fuel cells in series, the net voltage can be set high enough to charge a battery without use of additional electronics. Otherwise, a step-up DC-DC convertor is required. The DC-DC typically introduces voltage oscillations that can by our analysis result in degradation of the fuel cell power supply (Thangavelautham and Dubowsky, 2013). It also decreases the efficiency of the system due to voltage conversion losses.

Without the DC-DC convertor, the system is simpler and more efficient. In addition, a variable resistor circuit is included in the circuit. This variable resistor circuit is activated and used during start-up and shutdown, to ensure the fuel cell is at proper voltages at all times and to avoid fuel starvation. The variable resistor ensures the fuel cell maintains a constant voltage during start-up and shutdown. Finally, an electrical load is connected to the circuit and periodically turned on at a set duty cycle or on-demand. For sensor network applications, we wish to maximize both the life and fuel cell conversion efficiency to minimize hydrogen fuel consumption. The operating efficiency of a fuel cell given as a function of voltage is (Barbir, 2005):

$$\lambda_{FC} = 0.81V \quad (8)$$

Fig. 3 PEM fuel cell power supply for sensor networks. Drawn by Thangavelautham, J., Strawser, D., Dubowsky, S., 2017. The design of long-life, high-efficiency PEM fuel cell power supplies for low power sensor networks. *International Journal of Hydrogen Energy* 42, 20277–20296.

Fig. 4 Lithium Hydride Hydrolysis reaction with excess water. Credit from Strawser, D., Thangavelautham, J., Dubowsky, S., 2015. A passive lithium hydride based hydrogen generator for low-power fuel cells for long-duration applications. *International Journal of Hydrogen Energy*, 1–36.

A third constraint is that the fuel cells need to have matching output voltage to charge the battery. This is to avoid a specialized battery charging circuitry. A battery charging circuitry would add additional complexity to the system, and be a source of voltage oscillations and it will further reduce system efficiency due to conversion losses. A battery needs to be selected that has enough capacity so that when the load is powered, it does not result in a substantial voltage drain from the battery. This is once again to avoid voltage oscillations that degrade the fuel cell. This expected change in voltage due to loss of charge can be calculated from integrating a voltage-battery charge curve.

A power control system monitors the fuel cell output voltage and the battery. Once the voltage drops just below operating voltage range, the control system would divert output power from the fuel cell to charge the battery until the net voltage reaches the upper boundary of the operating voltage range. However, these rechargeable batteries increase the cost, complexity and reduce system robustness. These rechargeable batteries cannot provide power when there is a prolonged power shortage. Hence, the system needs to be designed to predict these shortages and have sufficient battery capacity to handle them.

Air, Water and Humidity Management

The purpose of the air and water management system is to ensure oxygen is delivered to the fuel cell cathode and ensure inert gasses such as nitrogen don't build-up in the anode. We assume that air-breathing PEM fuel cells are used; hence the oxygen is freely extracted from the air. However, it is critical that the air entering the cathode maintains a proper humidity to ensure smooth operation of the fuel cell. This requires that the air humidity not be too low or too high. Improper water management can result in loss of performance, prolonged flooding and shortened life (Kandlikar *et al.*, 2011). The results show that humidity needs to be well above 10% to avoid accelerated degradation. However, input humidity also cannot be too high, otherwise this might cause flooding that blocks pores in the GDL and cathode and result in reduced power output due to fuel starvation, oxygen starvation or both.

We can control the humidity of the fuel utilizing a feed-back control system. Once the humidity reaches beyond a set-point threshold, a vent opens to release the excess humidity into a dry environment. Furthermore, this controls approach can be made passive utilizing humidity sensitive material that can expand or contract (i.e., open or close) a vent. However, our laboratory studies shown these methods are unable to achieve humidity control within $\pm 10\%$ relative humidity.

A second objective as noted earlier is to prevent build-up of inert gasses such as nitrogen in the anode. The fuel cells as noted earlier are configured in a dead-end anode mode. This typically maximizes fuel utilization, but at a cost of build-up on nitrogen on the anode. If this is left unattended, a fuel cell will starve of hydrogen and drop in voltage. The net effect is that this degrades the fuel cell catalyst and limits life. A conventional method of removing the nitrogen is using a purge valve or material to release nitrogen upon build up.

Fuel Management

Here it is shown that lithium hydride is ideal for storage and release of hydrogen. Hydrogen can be released by exposing the hydride to water, releasing the hydrogen from the hydride and stripping water of its hydrogen according to the following reaction:

Lithium hydride unlike other water activated hydrides requires no complex mechanisms or catalysts to start, control and complete the reaction (Kong *et al.*, 1999; Strawser *et al.*, 2014). Our experimental studies show that water activated lithium hydride can achieve 100% reaction completion rates (see Fig. 4). Another appealing feature of water activated lithium hydride, for PEM fuel cells is that in theory, it produces enough waste water for activating the lithium hydride. When exhaust water from a fuel cell is

reused for producing more hydrogen using a lithium hydride generator, the reaction achieves a theoretical 25% hydrogen storage efficiency or 5000 Wh/kg specific energy (Strawser *et al.*, 2014) (40 folds higher than lithium ion batteries).

Several control strategies have been developed to produce the required hydrogen at high operating efficiencies. The passive hydrogen generator is designed not to carry water on board. Instead, it extracts water vapour from its surroundings and can work for humidity 15% and higher. This design is tested for long duration to produce hydrogen for a fuel cell power supply in (Strawser *et al.*, 2014; Thangavelautham *et al.*, 2017). The generator was designed to not carry water on-board. While passive lithium hydride generators relying on liquid water have been developed, this generator is unique in its ability to use water vapour from the atmosphere or fuel cell exhaust (Strawser *et al.*, 2014). Additionally, lithium hydride generators have not been experimentally validated for long periods of time or with a hybrid PEM fuel cell system. Based on the lessons learned, an experimental system was built to demonstrate the fuel cell power supply for field sensor networks.

The waste product from the lithium hydride hydrolysis reaction is lithium hydroxide. Lithium hydroxide is typically used as a CO₂ scrubber and the following reaction results in environment friendly lithium carbonate (Li₂CO₃) and water. Lithium carbonate exists as a natural mineral form called zabuyelite.

Applications

Consider a spherical sensor network node (Fig. 5) with a 10 cm radius. The node consists of 4 interchangeable modules, a central System on a Chip microcontroller module containing electronics, a wireless-radio, a power module consisting of either fuel cells or batteries and a payload module to house sensors. The payload module may contain temperature, humidity/moisture, vibration, accelerometers, chemical, light sensors and cameras. These nodes periodically communicate to neighbouring nodes and a central base station. Hence, they will be low-power devices that intermittently operate at high power to operate their payloads or communicate data. Each node will require a minimum 10 mW for standby power.

It is assumed the sensor modules consume 500 mW average. These nodes need to operate for 3–5 years unattended, without any periodic maintenance and have a mass less than 30 kg, so that it may be easily carried and deployed on site.

It is assumed that the field sensor is deployed in a temperate, desert or tropical location, operating continuously, where the temperature stays between 15 and 40°C and humidity varies between 0.15 and 0.9. In colder climates, the sensor node will require heaters to maintain the fuel cell temperature at 15°C or higher.

For environmental monitoring, the duty cycle can be low, utilizing environmental sensors (air, CO₂, temperature, humidity, soil moisture) that are typically low power devices with data being gathered periodically at duty cycles of 10% or less.

Battery Sizing

First batteries are considered as power supplies for these nodes. Batteries self-discharge, where stored energy is lost as heat and is modelled as a geometric series. It is further assumed that the last 20% of the stored energy cannot be used. The mass of a battery power supply required is:

$$M_{bat} = \frac{\alpha E(T)(1 - r^T)}{\rho_{bat}(1 - r)} \quad (11)$$

Where, M_{bat} is the total mass of the battery power supply required for T years of life, α is the capacity margin, r is the self-discharge rate, ρ_{bat} is the energy density of the battery, $E(T)$ is the energy required to power a payload device for T years according

Fig. 5 A sensor node for environmental monitoring of air quality and pollution readings. Drawn for the encyclopedia article by Jekan Thangavelautham.

to a given duty cycle. The energy densities, self-discharge rates and mass of the battery power supplies are shown in Table 4 (Thangavelautham and Dubowsky, 2013).

A sensor module weighing more than 30 kg or more lacks scalability to hundreds or even thousands of modules owing to the high cost and logistics required for transporting and installing them. Ideally, the sensor module and power supply needs to have low-mass that enables them to be carried in backpacks, mules and be readily deployed in off-grid environments.

Fuel Cell Sizing

Next, the proposed PEM fuel cell power supply concept is compared against batteries (Thangavelautham and Dubowsky, 2013). The mass of the fuel for the PEM fuel cell power supply is given by:

$$M_{fuel} = \frac{E(T)}{\rho_{fuel} \cdot r} \cdot \ln \left| \frac{0.5 - \frac{1}{r}}{T + 0.5 - \frac{1}{r}} \right| \quad (12)$$

where M_{fuel} is the total mass of the fuel for T years of life, ρ_{fuel} is the specific energy of the fuel, $E(T)$ is the energy required to power a payload device for T years for a given a power profile, r is the power degradation rate of the fuel cell power supply for a specified operating point. In addition, the dry mass of the power supply excluding the structural shell is given in Table 5. The lithium hydride fuel has a volume of 0.7 g/cm^3 . Based on these factors, the shell consists of an aluminium spheres, 1 mm thick, each with enough internal volume to hold the lithium hydride fuel.

The energy density of the fuel is given as follows:

$$\rho_{Fuel} = \rho_{LiH} \cdot \lambda_{FC_EH2} \cdot \eta_{LiH_RC} \quad (13)$$

Where, σ_{LiH} is the usable quantity of hydrogen energy released from the lithium hydride hydrolysis reaction (presuming water reuse), η_{LiH_RC} is the percentage reaction completion of the lithium hydride reaction and λ_{FC_EH2} is the efficiency of the fuel cell system.

The total efficiency of the fuel cell is calculated from the following:

$$\lambda_{FC_EH2} = \lambda_{FC} \cdot \lambda_{FC_Stack} \cdot \lambda_{Purge} \quad (14)$$

Where λ_{FC} is the chemical to electrical efficiency of the individual fuel cells and is related to the operating voltage of the cell, V/V_{LHV} , where V_{LHV} is 1.23 V, λ_{FC_stack} is the fuel cell stack efficiency and is 0.95, λ_{purge} is the losses due to nitrogen purging and is 0.95. Our work shows that operating each cell at 0.78 Volts, giving it a $\lambda_{FC}=0.63$ is a good trade-off between efficiency, life and power output. To supply peak system power and avoid oscillatory voltage seen by the fuel cell, the battery handles the high and varying power of the load.

To generate the average power required this requires 5 fuel cells or more. This design vastly simplifies the fuel cell control electronics. The fuel cells are assembled in this configuration to avoid a DC-DC convertor. With each fuel cell operating at 0.78 volts, 5 are assembled in series to obtain a nominal volt of 3.9 Volts. Note, that the mass calculated accounts for the extra fuel required due to losses from degradation and to ensure the fuel cell provides the energy required at the end of T years. Table 5

Table 4 Power supply technology characteristics

Technology	Specific energy (Wh/kg)	Self-discharge/degradation (% per month)
Alkaline	110	0.5
Lithium ion	140	5
Lithium CR	270	0.17
Lithium thionyl chloride	420	0.08
LiH fuel cell	5000	0.12

shows the mass breakdown of the fuel cell power supply. The power supply consists of the fuel cell, lithium hydride fuel storage system, power control electronics and other components for air and water management. The lithium hydride fuel produces hydrogen with the addition of water extracted from the air.

System Comparison between Battery and Fuel Cell

We first compare the proposed system with batteries. Fig. 6 shows the mass of the power system vs. average power of 0.5 W for 5 years of operation at 100% duty cycle. For very low power, batteries provide an advantage, because of the additional overhead mass required for the fuel cell power supply. The advantage for the fuel power supply is apparent when the system requires high-energy. Fuel cells using lithium hydride shows a 50-fold advantage in terms of mass compared to lithium ion batteries, a 7-fold advantage over Lithium CR batteries and a 3-fold advantage versus lithium thionyl chloride batteries. It should be noted that the rechargeable batteries weigh tens or hundreds of kilograms. For a network of hundred or thousand nodes, most of the batteries considered are not feasible. We also compare the proposed fuel cell power supply with previously reported fuel cell storage technologies (Fig. 7). These previously reported numbers are extrapolated to the required energy for mission lifetime.

This includes a PEM fuel cell powered using sodium borohydride and Direct Methanol Fuel Cells (DMFC). For these comparisons, the dry mass for these fuel cell configurations is assumed to be the same as the concept fuel cell system presented here. In addition, the operating efficiency of DMFC is lower at 40% and it outputs carbon dioxide that needs to be vented. DMFC offers a simpler approach to fuel storage, however, challenges exist with fuel cell life, due to build-up of carbon monoxide and low operating efficiencies. We presume these challenges have been overcome. The major difference is the mass and volume of the fuel and container.

Overall, for high duty cycle applications (see Fig. 8 left), the proposed fuel cell power supply offers a compelling advantage over other energy storage technologies. A LiH fuelled PEM fuel cell power supply of 78 kg can be fully operational for 5 years at 100% duty cycle and supply 2 W of power. In comparison, a lithium thionyl chloride primary battery system would weigh 360 kg. Overall, the proposed power supply offers a 4.6-fold mass advantage over the best battery technology and 5.25-fold advantage over DMFC.

In another scenario (Fig. 8 right), we consider powering a field sensor at 5% duty cycle for 5 years. This is equivalent to operating a sensor for 3 s every minute. The proposed fuel cell power supply can power a 20 W field sensor and have a total mass of 51 kg. In comparison, the lithium thionyl chloride battery would have a mass of 173 kg. The advantage of the lithium hydride fuel cell system is reduced mass for long duration missions.

Summary

Overall, the presented lithium hydride fuelled PEM fuel cell offers a substantial advantage over conventional batteries and other fuel cell and hydrogen technologies. These results present a promising pathway towards field testing and evaluation of the

proposed concept. For higher duty cycle applications, the proposed system shows an increased advantage over conventional technology. The mass advantage approaches nearly 5-folds over lithium primary batteries. This shows the promise in this technology for high-energy, remote, off-grid applications.

Nomenclature

(C_p)_{water} specific heat of water = 1 Kcal/Kg.

(CV)_{fuel} Calorific value of the fuel.

(CV)_{thread} Calorific value of thread = 4.18 Kcal/Kg.

(CV)_{wire} Calorific value of Nichrome ignition wire = .355 Kcal/Kg.

M_{fuel} Mass of the sample or biodiesel in grams.

M_{thread} Mass of the cotton thread in grams.

M_{water} Mass of the water in Kg.

M_{wire} Mass of the wire in grams.

ΔT Increase in the temperature of the surrounding water jacket.

Introduction

During the last century, the consumption of energy has increased substantially due to change in the life style and significant growth of population. This increase of energy demand has been supplied using fossil resources, which caused the crisis of fossil fuel depletion, the increase in the price and serious environmental impacts such as global warming, acidification, deforestation, ozone depletion, and photo chemical smog. As fossil fuels are limited sources of energy, the increasing demand of energy has led to a search of alternative sources of energy that would be economically efficient, socially acceptable, and environmentally sound. Petroleum based fuels consist of blends of hundreds of different chemicals of varying hydrocarbon chains, many of these are hazardous. Carbon monoxide (produced when combustion is incomplete), nitrogen oxides (produced when combustion occurs at very high temperature), sulphur oxides (produced when elemental sulphur is present in fuel), and particulates that are generally produced during combustion are other specific emission concern. So, it is time to search for its alternative fuels. There are several alternative sources of fuel like vegetable oils, biogas, biomass, primary alcohols which are all renewable in nature. Among these fuels, vegetable oils appear to have an exceptional importance as they are renewable and widely available, biodegradable, non-toxic and environmental friendly. Biodiesel refers to a family of products made from vegetable oil or animal fats and alcohol, such as methanol called mono alkyl esters of fatty acids. Study shows on the mass basis; biodiesel has energy content of about 12% less than petroleum based fuel. It reduces unburned hydrocarbons (HC), carbon monoxide (CO), and increase oxides of nitrogen (NO_x) than diesel fueled engine (Ayhan-Demirbas, 2007). Gas chromatographic system is widely applied technique in many branches of science and technology. For over a century, GC has played a fundamental role in determining how many components and in what proportion they exist in nature. In a gas chromatographic system, the ability to establish the nature and chemical structure of these separated and quantified compounds is ambiguous and reduced, and requires a spectroscopic detection system. In this system, the sample to be analyzed may be liquid solution or a collection of molecules adsorbed on a surface. During the transfer into the GC, the sample is volatilized by rapid exposure to a zone kept at relatively high temperature and mixed with a stream of carrier gas (Stashenko and Martínez, 2014). Biodiesel is a clean burning alternative fuel, produced from renewable resources like pure or used vegetable oil, both edible and non-edible. It can be used in compression-ignition (diesel) engines with little or no modification. Biodiesel is simple to use, biodegradable, nontoxic, and essentially free of sulphur and aromatic. It can be stored just like petroleum diesel fuel and hence does not require a separate infrastructure. The use of biodiesel in conventional diesel engines results in substantial reduction of unburned hydrocarbon, carbon monoxide and matter. Its high cetane number improves the ignition quality even when blended in petroleum diesel. Indian plants like *Jatropha* (*Atrophy curcas*), *Mahua* (*Madhuca Indica*), *Karanja* (*Pongamia pinnata*), and *Neem* (*Mellia* are widely used). In India, as edible oils are in short in supply, non-edible tree borne oilseeds of *Karanja*, *Jatropha*, *Mahua*, *Neem* are being considered as sources of straight vegetable oil and biodiesel (Radha and Manikandan, 2011). Plant species, which have 30% or more fixed oil in their seeds or kernel, have been identified. In India, edible oils are in short supply, and country must import up to 40% of its requirement. Hence prices of edible oils are higher than that of petroleum diesel. Most of the edible oils used currently for manufacture of Biodiesel, are stable. These do not decompose much on storage. Hence these are preferred for Transesterification process. Non-edible oils are not that stable, and need a lot of pre-treatment adding to the cost of manufacture of biodiesel. Government policy is also very important in production of biodiesel in India. Government of India started biodiesel mission in 2003, but it announced biodiesel policy on 11 September 2008. As per government policy, an indicative target of 20% by 2017 for the blending of biodiesel in diesel fuel and proposed biodiesel production will be taken up from non-edible oil seeds grown in waste, degraded, marginal lands. Biodiesel plantations on community, Government, forest waste lands would be encouraged while plantation in fertile irrigated lands. It was experimentally examined the Performance, emission and combustion characteristics of methyl esters of Punnai, Neem, Waste Cooking Oil and their diesel blends in a C.I. engine. For their study, Punnai oil methyl esters, neem oil methyl esters, and Waste Cooking Oil Methyl Esters were prepared by transesterification process. The Bio diesel-diesel blends were prepared by mixing 10%, 20%, 30%, and 40% of bio diesel with diesel. The effects of three methyl esters and their diesel blends on engine performance, combustion, and exhaust emissions were examined at different engine loads. Experimental results concluded that up to 30% of methyl esters did not affect the performance, combustion, and emissions characteristics

(Subramaniam *et al.*, 2013). On the other hand, above B30 (30% Biodiesel with 70% diesel) are reduction in performance, combustion, and emission characteristics were clear from the study. It was evident in the study that for all test fuels the brake thermal efficiency increased with increase in brake power. Among B10, B20, B30, B40, and B100 biodiesel, bio diesel blends up to B30 has a maximum brake thermal efficiency. With an increase in bio diesel blends the value of BSFC also increased. CO, CO₂, HC, NO_x, and smoke are the major exhaust emissions from C.I. engines. The diesel engine produces lesser amount of CO and HC emissions than spark ignition engines. Moreover, in case of bio diesel fueled engines, presence of airborne oxygen as well as its presence in the molecules of bio-diesel aids nearly complete combustion of fuel. The emission of diesel at maximum load was noted to be 960 ppm, whereas for B100 NOME it was noted to be 890 ppm. This reduced NO_x emission for B100 bio diesel when compared to diesel may be due to the reduced premixed combustion rate leading to lower NO_x emissions for B100 bio diesel operation. The experimental results proved that up to B30 blend of bio diesel-diesel blends, the performance and emission Characteristics were not much affected. When the blend ratio increased, incomplete Combustion takes place because of less time available for mixture formation, which leads to a reduction in the brake thermal efficiency of the engine as well as an increase in the emission level. The combustion analysis revealed that the overall combustion characteristics of B30 biodiesel blends were closer to diesel than pure bio diesel. Overall, the methyl esters of waste cooking oil proved improvements in performance and emission characteristics than the methyl esters of Punnai and Neem due to its closer physical and thermo-chemical properties to neat diesel (Liaquat *et al.*, 2013). It was studied the effect of storage on the physio-chemical properties of biodiesel produced from *Ricinus communis* (Castor), *Heavea brasiliensis* (Rubber), *Gossypium hirsutum* (Cotton), *Azadirachta indica* (Neem), *Glycin max* (Soyabean), and *Jatropha curcas* (Jatropha oils) stored in an open-air environment for a period of ten months. The peroxide value was found to be increasing with storage. However, since peroxide value is an index of oxidation of vegetable oil or its derivatives, it is obvious that oxidation of biodiesel takes place at rapid rate due to in built oxygen and unsaturated fatty acids (Muralidharan and Vasudevan, 2011). It has been conducted experiment with different blends (B10, B20) of neem oil and diesel at various loads. The results showed that the brake thermal efficiency of diesel is slightly higher at all loads followed by blends of neem oil and diesel, it has been established that 20% of neem oil biodiesel can be used as a substitute for diesel without any engine modification thus neem oil as non-edible oil can be a good renewable raw material for biodiesel production. From the experimental analysis, it was found that the blends of neem oil and diesel could be successfully used with acceptable performance up to a certain extent. Based on the result of this study properties of neem oil suggest that it cannot be used directly as CI engine fuel due to higher viscosity, density which will result in low volatility and poor atomization of oil during oil injection in combustion chamber causing incomplete combustion and carbon deposits in combustion chamber. Biodiesel blends produce lower brake thermal efficiency and higher brake specific fuel consumption than diesel because of low calorific value. The properties results of all blends show that blends up to 20% straight neem oil have value of viscosity and density equivalent to specified range for CI engine fuel, therefore it can be concluded that up to 20% blends can be used to run the CI engine at short term basis (Anbumani and Singh, 2010). It has been experimentally examined properties, performance and emissions of different blends (B10, B20, and B40) of PME, JME and NME in comparison to diesel. Results indicated that B20 have closer performance to diesel and B100 had lower brake thermal efficiency mainly due to its high viscosity compared to diesel. However, its diesel blends showed reasonable efficiencies, lower smoke, CO and HC. Jatropha and Neem based methyl esters (biodiesel) can be directly used in diesel engines without any engine modifications. Brake thermal efficiency of B10, B20 and B40 blends are better than B100 but still inferior to diesel. Properties of different blends of biodiesel are very close to the diesel and B20 is giving good results. It is not advisable to use B100 in CI engines unless its properties are comparable with diesel fuel. Smoke, HC, CO emissions at different loads were found to be higher for diesel, compared to B10, B20, B40 blends (Kumar *et al.*, 2013).

Methodology

Production of Biodiesel

To produce biodiesel from crude oil four process such as oil filtration, acid esterification, alkaline Transesterification and washing process, are used (Figs. 1–3).

Crude oil production

Coconut crude oil:

Seed = 22 kg, Extracted oil = 12.5 kg, Waste = 9.5 kg.

Yield = 56.81%

Castor crude oil:

Seed = 25 kg, Extracted oil = 9.5 kg, Waste = 15.5 kg.

Yield = 38%

Neem crude oil:

Seed = 25 kg, Extracted oil = 10 kg, Waste = 15 kg.

Yield = 40%

Mahua crude oil:

Seed = 23 Kg, Extracted oil = 9 Kg, Waste = 14 kg.

Fig. 1 Biodiesel Transesterification unit.

Fig. 2 Neem biodiesel.

Biodiesel production

Coconut biodiesel:

Crude Oil=12,300 ml, Produced Biodiesel= 11,380 ml, Yield=92.52%
Produced Glycerine= 2400 ml.

Castor biodiesel:

Crude Oil=8000 ml, Produced Biodiesel=7300 ml, Yield=91.25%
Produced Glycerine=750 ml.

Neem biodiesel:

Crude Oil=8500 ml, Produced Biodiesel=7700 ml, Yield=90.58%
Produced Glycerine=950 ml.

Mahua biodiesel:

Crude oil=7700 ml, Produced Biodiesel=6800 ml, Yield=88.31%
Produced Glycerine=700 ml.

Fig. 3 Neem biodiesel with glycerine.

Oil Filtration

Crude oil has higher moisture content and some other impurities. So in order to remove moisture and impurities oil is refined. The purification is done by boiling oil with 20% water. The boiling is continued until no bubble of water vapor anymore. After one hour the oil becomes clear. This refined crude oil is taken as raw material for esterification process.

Acid Esterification

This step is used for only those oils that have free fatty acids (FFA) more than 2%. Since Mahua, neem, castor oil have FFA about 9.4%, so this process is also used for these biodiesel. The crude oil is poured into a flask and heated up to 60°C. The 45% v/v methanol is added with preheated crude oil and stirred for few minutes, 0.5% of sulphuric acid is added with mixture. Heating and stirring is about 45 min at atmospheric pressure. Then the mixture is poured in to a separating funnel for separating excess methanol, impurities and sulphuric acid. The excess methanol, sulphuric acid and impurities move to the top layer and it is discarded. The lower layer is separated for transesterified it into methyl ester (Biodiesel). This process reduces the acid value of oil to 1% of FFA.

Alkaline Transesterification

Now esterifies oil is taken in flask and heated up to 60°C. 1% NaOH is dissolved in 30% methanol and dissolved solution is poured into flask. The mixture is heated and stirred about 750 rpm for one hour. Now the mixture is poured into separating funnel and left for 2 h. The glycerol and impurities are settled in lower layer by the gravity. The impure Biodiesel remain in upper layer. After discarding lower layer impure biodiesel drawn off which contain some trace of catalyst, glycerol, and methanol, this impure biodiesel is purified by washing process.

Washing Process

Purification of biodiesel is done by adding 3/4th of distilled hot water with impure biodiesel and shaking gently. The upper layer is of biodiesel and impurities collected into lower layer.

Experimental Setup

Castor, Coconut, linseed, mahua and neem biodiesel was used as a fuel with different blending ratios of B10, B20, B30, B40 and pure diesel (B00). For performance and emission testing of variable compression ratio (VCR) engine (**Fig. 4**) which has following

Fig. 4 Experimental setup.

specifications (**Table 1**): single cylinder 4-stroke multi-fuel water cooled engine, bore 87.5 mm, a stroke of cylinder 110 mm, the capacity of engine 661 cc, diesel power 3.5 kW, speed 1500 rpm, compression ratio range 12.1–18.1. Eddy current type dynamometer was connected to the engine for loading. Emission and performance test were conducted at different compression ratios of 15, 16, 17 and 18 under constant engine speed of 1500 rpm. We have used engine performance analysis software “Engine Soft.” For measuring the temperature at different zones, three types of sensors are used like RTD, PT 100 and Thermocouple, Type K. Digital voltmeter of range 0–20 V was used for display voltage, Strain gauge type load sensor was used of range 0–50 kg. A pipe type calorimeter was used for measuring the heat taken from exhaust gas with water flow rate of 25–250 lph. Engine cooling was done with water flow rate of 40–400 lph. To circulate water in engine and calorimeter self-priming pump was used. Starter motor was used for starting. Portable AVL digas 444 gas analyzer was used (**Table 2**). It measures the different constituents in exhaust gas like CO (vol %), CO₂ (vol %), NO_x (ppm), unconsumed oxygen O₂ (vol %) in the exhaust and unburnt HC (ppm). Setup of VCR engine consists of stand-alone type independent panel box consisting of fuel tank, fuel measuring unit, digital speed indicator, air box, manometer and digital temperature indicator (**Table 3**). Air box measured air flow rate. The cylinder pressure was recorded at the crank angle for each 1-degree increment. Two types of tests i.e., leakage test and hydrocarbon residue test were conducted before measurement of exhaust gas constituents. Leakage test was performed for 24 s, if the result is ok then no problem, but in any case, the test fails means leakage is found then the whole test has to be conducted again. Similarly, hydrocarbon residue test was conducted for 80 s.

Properties Measurements

Calculation of Lower Calorific Value

Calorific value is the amount of heat energy released by the combustion of a unit value of fuel (**Table 4**). Calorific value of biodiesel is calculated by bomb calorimeter (**Fig. 5**) present in IC engine laboratory. It is a constant volume calorimeter used in measuring the heat of combustion. In the present calorimeter design, the bomb is pressurized with pure oxygen at 25–30 bar, containing a known mass of fuel. It submerged under the known volume of water. The bomb forms a closed system. The bomb is ignited electrically. The energy released by the combustion raise the temperature of the bomb and the surrounding water jacket.

Calorific value is calculated by the following formula:

$$M_{\text{fuel}} * (CV)_{\text{fuel}} + M_{\text{thread}} * (CV)_{\text{thread}} + M_{\text{wire}} * (CV)_{\text{wire}} = M_{\text{water}} * (C_p)_{\text{water}} * (\Delta T)$$

Where: M_{fuel} = Mass of the sample or biodiesel in grams.

M_{thread} = Mass of the cotton thread in grams.

M_{water} = Mass of the water in Kg.

M_{wire} = Mass of the wire in grams.

$(CV)_{\text{fuel}}$ = Calorific value of the fuel.

$(CV)_{\text{thread}}$ = Calorific value of thread = 4.18 Kcal/Kg.

$(CV)_{\text{wire}}$ = Calorific value of Nichrome ignition wire = .355 Kcal/Kg

$(C_p)_{\text{water}}$ = specific heat of water = 1Kcal/Kg.

ΔT = Increase in the temperature of the surrounding water jacket.

Viscosity

Viscosity is the property of fluid by which it offers resistance to flow (Table 5). It affects the injector lubrication and fuel atomization. Fuel with low viscosity may not provide sufficient lubrication for the precision fit of fuel injector pumps resulting in leakage or increased wear. Fuel atomization is also affected by fuel viscosity. Fuel with low viscosity tends to form smaller droplets on injection which cause good combustion and vice-versa. Through transesterification and washing process it is decreased and comes very close to diesel. Viscosity of crude oil and biodiesel is measured by Brookfield viscometer (Fig. 6) present in fluid mechanics laboratory.

Flash Point and Fire Point

The flash point temperature of a fuel is the minimum temperature at which the fuel ignites (flash) on application of an ignition source under specific condition. Flash point varies inversely with the fuel volatility. Minimum flash point temperature is required for proper safety and handling of fuel. The fire point of a fuel is temperature at which the vapor produced by the test

Fig. 7 Flash point and Fire point tester.

fuel continues burning for at least 5 s after ignition by an open flame. At flash point which is lower than fire point (**Table 6**), a fuel ignites briefly but vapor might not at sufficient rate to sustain the fire. These values have observed by performing experiment on flash and fire point tester (**Fig. 7**).

Gas Chromatography

Gas chromatography (GC) is a common type chromatography used in analytical chemistry for separating and analyzing compounds that can be vaporized without decomposition. Typical uses of GC include testing the purity of a particular substance, or separating the different components of mixture (relative compounds of such components can also be determined).

Structure of Gas Chromatography

In gas chromatography, the mobile phase or moving phase is a carrier gas, usually an inert gas such as helium or nonreactive gas such as nitrogen. Helium remains the most commonly used carrier gas in about 90% instrument although hydrogen is preferred for improved separations. The stationary phase is a microscopic layer of liquid or polymer on a inert solid support inside a piece of glass or metal tubing called column, through which different chemicals constituents of a sample pass in a gas stream (carrier gas, mobile phase) at different rates depending on their various chemical and physical properties and their interaction with a specific column filling called stationary phase. The function of the stationary phase in the column is to separate different components, causing each one to exit the column at a different time (retention time).

Principle of Working of Gas Chromatography

Flame ionization detector (FID)

Flame ionization detector is a scientific instrument that measures the concentrations of organic species in a gas stream. It is a frequently used as a detector in gas chromatography. The operation of the FID is based on the detections of the ions formed during combustions of organic compounds in a hydrogen flame. The generations of these ions are proportional to the concentrations of organic species in the sample gas stream.

Thermal conductivity detector (TCD)

Thermal conductivity detector is a common detector relies on the thermal conductivity of matter passing around a tungsten filament with a current travelling through it. In this set up helium or nitrogen serve as the carrier gas because of their relatively high thermal conductivity which keeps the filament cool and maintain uniform resistivity and electrical efficiency of the filament. However, when analyze molecules elute from the column, mixed with carrier gas, thermal conductivity decreases and this causes detector response. The response is due to the decreased thermal conductivity causing an increase in filament temperature and resistivity resulting in fluctuations in voltage.

Parameters of GC for FAME Analysis

Analytical Method Parameter:

Column: SUPELCOWAX 10 (30 × .25 mm inner diameter × .25 μm film).

Injection Volume: 1 μL

Split ratio: 10:1

Inlet temperature: 250°C

Constant flow: 1 mL/min helium

Oven temperature: 100°C for 1 min, 25°C/min up to 200°C and hold for 1 min, 5°C/min up to 250°C and hold for 7 min.

FID: 280°C

Fame sample: Fame mix C8–C24.

Result and Discussions

Performance Characteristics

Brake thermal efficiency (BTE)

Figs. 8–15 show the variation of brake thermal efficiency to different blending for different biodiesel and pure diesel for different loading conditions at compression ratio of 18. It has been observed that brake thermal efficiency increases with increasing load. From the figure it has been observed that brake thermal efficiency is lower at minimum load. This is due to high fuel-air ratio which leads to incomplete combustion and most of the fresh charge remains unburnt. At higher loads brake thermal efficiency is continuous increasing. This is due to complete combustion of fuel; lower losses are encountered at higher load and brake thermal efficiency increases with load (Liaquat *et al.*, 2013; Muralidharan and Vasudevan, 2011). Brake thermal efficiency is directly proportional to the compression ratio. Brake thermal efficiency is obtained maximum 43.04% for castor biodiesel at full load at B20 and its obtained minimum 1.58% for Neem biodiesel at zero load at B40 in December month. Brake thermal efficiency is obtained maximum 46.52% for neem biodiesel at full load at B40 and its obtained minimum 2.08% for Mahua biodiesel at zero loads at B30 in June month. It observed from figure of December and June that brake thermal efficiency increases for all blending. This may due to blends fuel density, heating value, viscosity of the fuel (Liaquat *et al.*, 2013).

Variation of brake thermal efficiency with load in the month of December:

Brake power

Figs. 16–23 show the variation of brake power at a different load of different blending of castor, coconut, linseed, mahua, neem biodiesel and pure diesel at compression ratio 18. It indicates that brake power increases linearly with increasing the load and maximum at full load. Brake power decreases at high compression ratio due to the conversion of chemical energy to mechanical energy (Subramaniam *et al.*, 2013). Due to lower heating value of blends of biodiesel, brake power decreases (Liaquat *et al.*, 2013). Brake power is obtained maximum 3.66 kW for Mahua biodiesel at full load at B10 and its obtained minimum .5 kW for Neem biodiesel at zero loads at B40 in December month. Brake power is obtained maximum 3.56 kW for coconut biodiesel at full load at B20 and its obtained minimum .06 kW for Linseed biodiesel at zero loads at B30 in June month. It concluded from graph of December and June month brake power decreases with storage time of biodiesel blends.

Mechanical efficiency

Figs. 24–31 show the variation of mechanical efficiency at different load for different blending for castor, coconut, linseed, Mahua, Neem biodiesel and pure diesel at compression ratio 18. It has been observed that mechanical efficiency increases with increasing load for all blends B10, B20, B30, B40, and pure diesel. It has been observed that mechanical efficiency increase with increasing the proportion of blends in the diesel. Mechanical efficiency is obtained maximum 58.42% for linseed biodiesel at full load at B30 and its obtained minimum 2.04% for linseed biodiesel at zero loads at B10 in December month. Mechanical efficiency is obtained maximum 78.65% for coconut biodiesel at full load at B30 and its obtained minimum 1.6% for Neem biodiesel at zero loads at

Variation of mechanical efficiency with load in the month of June:

Exhaust Gas temperature

The Exhaust Gas Temperature (EGT) is an indication of effectiveness of utilization of heat energy produced by combustion of fuel. Figure shows that the Exhaust gas temperature increases as load increases for both diesel and biodiesel blending because increase in load increases amount of fuel supply which leads to high exhaust gas temperature. It is observed that the exhaust gas temperature for biodiesel blends is lesser than diesel. Figs. 32–39 show that exhaust gas temperature of biodiesel blending decreases with increasing blending due to increasing viscosity which leads to poor atomization, vaporization and therefore exhaust gas temperature of biodiesel decreases. Exhaust gas temperature obtained maximum 279°C for linseed biodiesel at full load at B10 and obtained minimum 112°C for pure diesel at zero load in December. Exhaust gas temperature obtained maximum 323°C for coconut biodiesel at full load at blending B30 and obtained minimum 110°C for castor biodiesel at zero load at blending B20 in June.

Emission Characteristics

Carbon monoxide (CO)

Figs. 40–47 show the variation of carbon mono oxide emission with castor, coconut, linseed, Mahua and neem biodiesel blends and pure diesel at different load at compression ratio 18. It forms due to incomplete combustion of fuel, which is caused by lack of oxidants, residence time, and mean temperature. The percentage of CO decrease with increasing load and compression ratio due to rising temperature in combustion temperature, physical and chemical properties of the fuel, air-fuel ratio, shortage of oxygen at high speed, lesser time available for the combustion of the fuel (VenkateswaraRao *et al.*, 2008). CO emission is obtained maximum .08 vol% for castor biodiesel at zero. Load at B10 and its obtained minimum .02 vol% for coconut biodiesel at full loads at B10 in December month. CO emission is obtained maximum .09 vol% for castor biodiesel at zero loads at B20 and its obtained minimum .02 vol% for linseed biodiesel at full load at B30 in June month. It concluded from results of December and June month CO emission almost remains constant with storage time of biodiesel blends.

Variation of CO emission with load in the month of June:

Hydrocarbon (HC)

Figs. 48–55 show the variation of HC emission of castor, coconut, linseed, Mahua and neem biodiesel blends and pure diesel at varying load at compression ratio 18. It has been observed from graph that as load increases, HC emission decreases and as compression ratio decreases, hydrocarbon emission decreases, this is due to the fuel consumption increases with load and more fuel injected in the cylinder, temperature increases and complete combustion takes place. The unburnt hydrocarbon is the product of incomplete combustion. As load increases the temperature inside the cylinder increases which helps in complete combustion of fuel and unburned hydrocarbon decreases. HC emission is obtained maximum 29 ppm vol. for castor biodiesel at zero loads at B10 and its obtained minimum 12 ppm vol. for coconut biodiesel at full load at B20 in December month. HC emission is obtained maximum 29 ppm vol. for castor biodiesel at zero loads at B40 and its obtained minimum 15 ppm vol. for neem biodiesel at full load at B40 in June month. It is concluded from results of December and June month, CO emission almost remains constant with storage time of biodiesel blends.

Variation of HC emission with load in the month December:

Variation of HC emission with load in the month of June:

Oxides of nitrogen (NOX)

Figs. 56–63 exhibits the variation in NO emission with load at the different blending of castor, coconut, linseed, Mahua and neem biodiesel and pure diesel at compression ratio 18. From the literature, it is revealed that NO is directly proportional to the power output of the engine because NO emission increased with increase in combustion and exhaust temperature (Yogesh Tamboli *et al.*, 2013). The present test results shows that NO emission increase almost linearly with increasing load because of higher cylinder pressure and higher temperature (ADemirbas, 2003). NO emission increase with average of 1.2% for diesel and for biodiesel blends increases with 2.25% with compression ratio. NO_x emission is obtained maximum 730 ppm vol. for coconut biodiesel at full load at B10 and obtained minimum 106 ppm for coconut biodiesel at zero loads at B20 in December month. NO_x emission is obtained maximum 450 ppm vol. for coconut biodiesel at full load at B10 and its obtained minimum 83 ppm vol. for neem biodiesel at zero loads at B40 in June month. It concluded from graph of December and June month oxides of nitrogen decreases with storage time of biodiesel blends.

Variation of NO emission with load in the month of December:

Variation of NO emission with load in June month:

Conclusion

During the present investigation, several tests were carried out on four strokes single cylinder water-cooled direct injection diesel engine using diesel, castor, linseed, mahua, neem biodiesel with different volume proportion. The experimental results confirm that brake power, mechanical efficiency, brake thermal efficiency, carbon monoxides, oxides of nitrogen are functions of biodiesel blends, and compression ratio. From the experiment following conclusions were drawn:

- Brake Power decreases with increasing the compression ratio, and it is maximum 3.47 kW for pure diesel. Minimum brake power for biodiesel blends and minimum obtained 3.25 kW linseed biodiesel at compression ratio 18.
- It was observed that the brake thermal efficiency was maximum for B20 and increases as load increases at compression ratio 18.
- Mechanical efficiency is also increasing with load. Diesel has the better mechanical efficiency compare to all blends of the coconut biodiesel but blend B50 shows the ME near to pure diesel at CR 18.
- Increasing compression ratio there was a significant reduction in the CO. CO emission increases with increasing the blending. Minimum for linseed biodiesel at B20 is .05% at compression ratio 18 and maximum for diesel is .22% at compression ratio 15.
- NO_x emission increases with increase in compression ratio. For higher blending proportions NO_x emission were also higher. Maximum NO_x emission was obtained 403 ppm for castor biodiesel at compression ratio 18 at B10, and minimum emission was obtained 145 ppm for diesel at compression ratio 15.

Sustainable Cutting Fluids: Thermal, Rheological, Biodegradation, Anti-Corrosion, Storage Stability Studies and its Machining Performance

Kishor K Gajrani and Mamilla R Sankar, Indian Institute of Technology, Guwahati, India

Introduction

The demand for energy is increasing day by day due to ever-going development, modernization and industrialization. The energy consumption by world is estimated to increase by 33.5% from 2010 to 2030 (Saidur *et al.*, 2011). Fossil fuels are one of the most commonly used sources of energy. In general, fossil fuels are used in the form of fuel and lubricant to fulfil soaring energy demand. Survey estimation says that 30–40 million tons of lubricants are used every year. Out of these, 20 million tons come back to the environment after usage (Mang and Dresel, 2017). Most of these lubricants (over 95%) that end up in the environment are based on petroleum products (Schneider, 2006).

Petroleum-based cutting fluids are subdivided into two categories; straight oils and neat oils. Both consists performance enhancer additives to improve its various properties. Additives such as fatty material, free sulphur, chlorinated paraffin, sulphurized oils and phosphorus compounds are present in petroleum-based cutting fluids (Dixit *et al.*, 2012). At higher temperature these additives react with work material and form metal chloride, phosphates as well as sulphides, which are hazardous and harmful to the environment (Trent, 2000; Gajrani and Sankar, 2017a). In long run, inappropriate disposal of used petroleum-based cutting fluids can cause serious damage to environment. Moreover, prolong exposure to emissions of the cutting fluids causes several types of cancers as well as respiratory diseases (Sankar and Gajrani, 2017). Also, petroleum-based lubricants are non-renewable. A global concern has aroused due to environmental hazard and gradual depletion of petroleum source.

Nowadays to minimize these concerns, several alternative measures such as development of environment friendly cutting fluids and green energy systems are focused (Nagendramma and Kaul, 2012; Bart *et al.*, 2013; Somashekaraiah *et al.*, 2016). Therefore, bio-based cutting fluids or bio-cutting fluids (BCF) are derived using bio-based raw materials such as animal fats, vegetable oils, unsaturated acids, etc., (Salimon *et al.*, 2010). From recent past, BCF production is growing with agricultural advancement. As per the estimation of United States Department of Agriculture (USDA), 185.72 million metric tons vegetable oil will be produce in 2016/17 (USDA, 2016). Most BCF have almost similar molecular structure. They mainly consist of triglycerides. Triglycerides have number of long unsaturated fatty acids chains (Fox and Stachowiak, 2007; Mongkolwongrojn and Arunmetta, 2002), which are renewable and readily biodegradable. In addition, BCF have high viscosity index and high flash point than that of petroleum-based mineral oils (MO) (Soni and Agarwal, 2014). High viscosity index of BCF ensures better stable lubricity, which means with the increase in temperature viscosity of BCF drops slowly as compared to petroleum based MO (Woods, 2005). Also, high flash point of BCF reduces possibilities of fire hazard and smoke formation. Moreover, BCF have higher boiling point and heavier molecular weight that reduces vaporization and mist formation (Khan and Dhar, 2006). Further, BCF is capable of reducing friction and wear between two mating surfaces. It is due to ability of polar and long carbon unsaturated acid chain to strongly interacting with intermetallic surface. Apart from above mentioned characteristics, BCF is sustainable, biodegradable and highly renewable source. Therefore, BCF can be a viable alternative to petroleum-based cutting fluids. Fig. 1 illustrates life cycle of renewable resources based products (Willing, 2001).

In spite of numerous merits, usage of BCF is still limited today. It is due to major issues regarding their cost and performance. However, most of the researchers have used BCF with minimum quantity lubrication (MQL) also known as minimum quantity cutting fluid (MQCF) technique to reduce cost by minimizing its consumption (Boswell *et al.*, 2017; Khandekar *et al.*, 2012; Heinemann *et al.*, 2006). As per the performance is concern, these insufficiencies can be improved by the addition of proper additives and chemical modifications. These additives and modification changes the properties of BCF. With proper knowledge, BCF properties can be altered and controlled in a desired way. Therefore, it is necessary to investigate various properties of BCF. Furthermore, constant activities among government organizations, environmental agencies and manufacturer will results in development of procedures for the implementation of bio-technologies that can benefit ecological, social and economic aspects. In long run, there hard work can lead in sustainable environmental management and assessment (Walters, 1986).

In this study, physical properties of BCF are characterized. Also, thermal, rheological, apparent activation energy, biodegradable potential, anti-corrosion and storage stability characteristics of BCF are investigated. For comparison, similar studies are also conducted with MO. Afterwards, machining experiments using minimum quantity cutting fluids (MQCF) technique are carried out to examine the relative machining performance of both cutting fluids in terms of cutting force, feed force, coefficient of friction and surface roughness.

Physical Characterization of Cutting Fluids

The cutting fluids used for this study are petroleum-based MO and sustainable BCF. The MO used in this study was supplied by Servo Lubricants and Greases, Indian Oil Corporation Limited, India and BCF by CORTEC Corporation, India. BCF and MO are

characterized. Flash point of cutting fluids are measured using Pensky-Martens open cup setup in accordance with EN ISO 2719 (ECS, 2003) standard (Janes and Chaineaux, 2013). A Varian digital pH meter is used to measure pH of the cutting fluids.

Both BCF and MO are characterized and their physical properties are illustrated in Table 1 (Gajrani *et al.*, 2017b). BCF have more density and less pH as compared to MO that suggest that BCF is less basic among them. BCF have high flash point, which suggests that it can be used even for higher temperature applications and it is safer during hard machining as compared to MO.

Thermal Stability of Cutting Fluids

Stability of the molecule at high temperatures is known as thermal stability; i.e., molecule which offers more resistance to degradation at higher temperature is termed as more stable molecule. Cutting fluid thermal stability is the measure of its mass loss with varying temperature, which can be investigated using thermal gravimetric analysis (TGA).

Twenty mg of each cutting fluids in alumina crucible are tested for thermal degradation studies using thermal gravimetric analysis setup (Make: NETZCH Instruments, Model: STA F4913). Samples are tested in the range of 50–700°C with heating rate of 10°C min⁻¹. Tests are carried out under argon atmosphere (argon flow rate=60 mL min⁻¹).

Fig. 2 illustrates the thermal degradation behaviour of BCF and MO with respect to temperature (Gajrani *et al.*, 2016). The result shows that both cutting fluids have similar behaviour in terms of mass loss. However, they have different starting degradation temperature. BCF degradation starts at 118°C, which shows a better thermal stability as compared to MO whose degradation starts as 51°C.

In case of BCF, upto 100°C no mass loss was observed, which shows the absence of water in it. BCF degrades $13.33 \pm 1\%$ of its mass up to 200°C, which is much lower than MO mass degradation ($28.54 \pm 2\%$). After 466°C, mass almost become constant. This is attributed to already decompose higher molecular mass components of BCF. Maximum mass loss of $91.2 \pm 2\%$ was observed for BCF. Mass loss with temperature is due to the combination of both degradation and volatilization.

In case of MO, over 10% mass degrades before 100°C, which confirms the presence of small carbon chain groups and moisture in it. Up to 460°C, around $90 \pm 3\%$ mass loss was observed. After experiment, around $4 \pm 3\%$ mass was still remaining, which

Fig. 2 Mass loss of bio-cutting fluid and mineral oil with respect to temperature. Reprinted with permission from Gajrani, K.K., Suvin, P.S., Kailash, S.V., Sankar, M.R., 2016. Comparative studies on thermal, rheological behaviour of eco-friendly cutting fluids and their machining performance. indicates the presence of formation of coke (carbon derived from pyrolysis of organic compound) or inorganic compound. MO has lower thermal stability as compared to BCF. Therefore, BCF can be used at high temperature application like hard machining.

Shear Stress and Viscosity of Cutting Fluids

The flow and lubricant behaviour of cutting fluid depends on its shear stress and viscosity. Therefore, shear stress and viscosities of cutting fluids are measured as a function of shear rate using a rheometer (Make: ANTON PAAR[®], Model: MCR-101) with a coaxial cylinder tool master. To obtain shear flow conditions, experiments are conducted under steady flow state. Measurements were carried out by linear increase in shear rate from 1 – 1000 s⁻¹ at four different temperatures of 20°C, 50°C, 80°C and 100°C. Average values of three tests are reported.

It is obvious that BCF cannot follow the same mechanism for lubrication as MO. Lubrication depends on various properties such as viscosity, density, composition, etc. However, cutting fluid viscosity is the most important among them. Cutting fluids having higher viscosity are believed to have better lubricating properties.

Apparently viscosity can decrease, remain unchanged or increase with respect to shear rate for time dependent fluids. These fluids are known as pseudoplastic ($n < 1$), Newtonian ($n = 1$) and dilatant ($n > 1$), respectively. It is important to know the behaviour of cutting fluid because various metalworking processes involve different operating range of temperature and shear rate.

Fig. 3(a – d) shows the effect of shear rate on shear stress of BCF and MO at 20°C, 50°C, 80°C and 100°C, respectively (Gajrani *et al.*, 2016). Even though the chemical composition of BCF and MO is different, their rheological behaviour is similar. Both cutting fluids shows near Newtonian behaviour ($n = 1$) at 20°C (**Fig. 3(a)**) and 50°C (**Fig. 3(b)**). Newtonian behaviour can be confirmed by the linear variation of shear stress with shear rate. However, at the higher temperature of 80°C (**Fig. 3(c)**), only BCF shows near Newtonian behaviour. At higher shear rate, MO exhibits the dilatant behaviour. With the further increase in temperature at 100°C (**Fig. 3(d)**) both cutting fluids exhibits dilatant behaviour after shear rate of 500 s⁻¹. Therefore, it can be said that BCF is able to maintain Newtonian behaviour at higher temperature as compared to MO.

Fig. 4(a–d) illustrates the effect of shear rate on viscosities of BCF and MO at 20°C, 50°C, 80°C and 100°C, respectively (Gajrani *et al.*, 2016). At 20°C, viscosities of BCF and MO are 0.12 Pa.s and 0.05 Pa.s, respectively. However, due to high heat and temperature during metalworking operations, cutting fluids mostly operate much above 20°C. Therefore, viscosities of BCF and MO at higher temperature are also reported. At 50°C, viscosities of BCF and MO are 0.03 Pa.s and 0.015 Pa.s, respectively. Furthermore, with increase in temperature, the viscosities of BCF and MO are 0.011 and 0.007 Pa.s, respectively at 80°C as well as 0.007 and 0.004 Pa.s, respectively at 100°C. With increase in temperature, viscosity of both cutting fluid reduces. It is attributed to molecules that overcome a threshold energy barrier and occupy the adjacent vacant site due to thermal activation. For varying temperature range, BCF has more viscosity as compared to MO that enables it to lubricate better as compared to MO.

Apparent Activation Energy of Cutting Fluids

Flow of molecules is a thermally activated process. In any liquid, molecules need to overcome an energy barrier to flow to the nearby vacant site. With the increase in temperature, the number of vacant sites in the liquid increases as well as molecules own thermal energy also increases. The dependence of the reaction rate on the temperature indicates the apparent activation energy. The term activation energy is defined as minimum necessary energy required for the occurrence of a specific chemical reaction. Arrhenius type equation relates the viscosity (μ) and the activation energy (E_a) as follows:

$$\mu = A \exp\left(\frac{E_a}{RT}\right) \quad (1)$$

Fig. 3 Effect of shear rate on shear stress of mineral oil and bio-cutting fluid at (a) 20°C, (b) 50°C, (c) 80°C and (d) 100°C. Reprinted with permission from Gajrani, K.K., Suvin, P.S., Kailash, S.V., Sankar, M.R., 2016. Comparative studies on thermal, rheological behaviour of eco-friendly cutting fluids and their machining performance. In: Proceedings of the 6th International and 27th All India Manufacturing Technology Design and Research (AIMTDR) Conference, pp. 674 – 678. Pune: COEP. Copyright [2016], Copyright holder [AIMTDR].

where T is the absolute temperature, R refers to real gas constant and A is a constant. Activation energy is determined using temperature dependence of viscosity with the help of Eq. (1) (Moraes *et al.*, 2011; Qi-Wei *et al.*, 2003). Eq. (1) can be rewritten as:

$$\ln(\mu) = \ln(A) + \left(\frac{E_a}{R}\right) \frac{1}{T} \quad (2)$$

Fig. 5 shows the variation of viscosities with respect to temperature for BCF and MO. Viscosity of both cutting fluid reduces with increase in temperature. It is attributed to reduction in intermolecular forces between molecules with increase in temperature. Using Eq. (2) and data from Fig. 5, a relation between $\ln(\mu)$ against T^{-1} is plotted as shown in Fig. 6 (Gajrani *et al.*, 2016). From the slopes of $\ln(\mu)$ against T^{-1} , apparent activation energy is calculated and reported in Table 2 (Gajrani *et al.*, 2016). BCF have high activation energy that means BCF is less sensitive and more stable with increasing temperature as compared to MO.

Biodegradability of Cutting Fluids

The term biodegradation represents breakdown of any substance by micro-organism such as enzymes, fungi, bacteria etc. and the substance own ability to biodegrade is called biodegradability. Biodegradation is classified into two categories: Primary biodegradation and ultimate biodegradation. Primary biodegradation means change in physical and chemical characteristics of the matter or substance due to activities of micro-organism. Further, ultimate biodegradation is described as total (full) conversion of matter or substance into biomass, water, carbon dioxide, methane and mineral salts.

The aim of cutting fluid biodegradation study is to measure ultimate biodegradability. In general, ample amount of oxygen and water (aerobic aquatic biodegradation environment) is needed for biodegradability test of cutting fluids. For measuring life cycle of any liquid matter or substance, its dissolved oxygen (DO) is an important element. To measure the oxygen demand for degradation of both non-biodegradable oxidisable matter/substance and biodegradable matter/substance, chemical oxygen demand (COD) tests are carried out. However, biological oxygen demand (BOD) test give only measure of oxygen demand for degrading organic matter in cutting fluid (only cutting fluid's biodegradable portion). Therefore, the ratio of BOD/COD quantifies the biodegradable potential of cutting fluids.

Fig. 5 Effect of temperature on viscosity of mineral oil and bio-cutting fluid.

For primary biodegradation, five days BOD and COD tests are carried out using 1:100000 (lubricant: Aerated water) diluted samples of BCF and MO. Afterwards, least square method is used to calculate ultimate BOD (BOD_u) for complete biodegradation information in accordance with *Standard Methods 2005* (American Public Health Association) (APHA, AWWA, WPCF, 2005).

BOD test for a period of five days is known as BOD_5 . The degradation potential of biodegradable substance is indicated by BOD_5/COD ratio. Therefore, BOD_5/COD ratios of BCF and MO at different times are used to assess the biodegradation potential of cutting fluids (Fig. 7) (Gajrani et al., 2017b).

It is well known that the cutting fluids biodegradability primarily depends on organic content and their chemical structure. It is observed that over the five days, MO degraded around 10%; however, BOD_5/COD ratio for BCF is well over 40%. This is attributed to composition of BCF. BCF consist high amount of organic matter which degrades easily. However, MO is mostly made up of fixed solids or non-degradable volatile solids. For five days biodegradability test, BOD_5/COD ratio over 0.4 for any chemicals/

waste water/substance is considered completely degradable (Adams *et al.*, 1979). In contrast, BOD_5/COD ratio under 0.2 falls under the category of highly non-degradable in nature due to presence of unoxidisable organic matter in high amount. However, BOD_5/COD ratio only provides preliminary information about cutting fluids biodegradability.

For total biodegradation, ultimate BOD (BOD_u)/COD ratio provides complete information. As per *Standard Methods 2005*, least square method is used for calculating BOD_u (APHA, AWWA, WPCF, 2005). Table 3 shows the calculated ultimate aerobic biodegradability of BCF and MO (Gajrani *et al.*, 2017b). BOD_u for BCF is 1392 g/L; however, BOD_u for MO is only 417.8 g/L. In contrast, COD for BCF is only 1440 g/L while for MO is 2280 g/L. From Table 3, it is observed that BOD_u/COD ratio for BCF is well over 0.8 that is considered readily and highly biodegradable for any matter (Adams *et al.*, 1979). The atmospheric present natural bacteria can easily oxidised cutting fluids containing organic matter which is shown by high BOD_u value.

Table 3 Ultimate aerobic biodegradability of mineral oil and bio-cutting fluid

Metal cutting fluid	BOD_u ultimate (g/L) (least square method)	COD (g/L)	BOD_u/COD	Final degradation (%)
Mineral oil	417.8	2280	0.1832	18.32
Bio-cutting fluid	1392	1440	0.9667	96.67

Fig. 8 Overview of corrosion test method setup (a) filter paper with petri dish, (b) grey cast iron chips on the filter paper and (c) cutting fluid poured into petri dish.

MO exhibits very low biodegradation. MO based cutting fluids are more inclined towards metallic cations. Those are hazardous to sewage micro-organism, which further reduces the plant disposals efficiencies. Ultimate biodegradability predicts the capacity of natural water bodies/sewage micro-organism to degrade BCF without any external factor. However, during incubation time, MO does not show satisfactory degradation. Therefore, un-decomposed matter of MO may appear as pollutants in the environment.

Anti-Corrosion Properties of Cutting Fluids (ASTM D 4627)

Cutting fluids corrosion tests are performed in accordance with ASTM D 4627 standard (ASTM D, 4627, 2012). **Fig. 8(a)** illustrates 47 mm diameter filter paper made of glass fiber (1.5 μ m particle retention) placed inside the petri dish. Cutting fluid with ten different oil concentration (0.5, 1, 1.5, 2, 2.5, 3, 4, 5, 7 and 10%) of each BCF and MO were mixed with synthetic hard water (calcium chloride dehydrate in distilled water). As per the standard, grey cast iron chips are selected for corrosion tests. Chips were sieved using 18 mesh screen. **Fig. 8(b)** illustrates 4 g of chips sprinkled on the top of glass fiber filter paper. Afterwards, different petri dishes were filled with 25 mL of ten varying oil concentration of BCF and MO each. **Fig. 8(c)** shows chips submerged in cutting fluids. All petri dishes were covered with top lid. After incubation time of 24 h, cutting fluids were drained from petri dish. Afterwards, corroded chips were collected separately. Chips were cleaned by sonication using acetone for 20 min and dried. Chip weight loss due to its corrosion was also calculated. Moreover, glass fiber filter paper was rinsed. The amount of rust stain over the filter paper gives measure of cutting fluid anti-corrosion properties that helps in identifying breakpoint. ASTM D4627 defined breakpoint as the weakest concentration of cutting fluid tested, which shows no rust stain on the glass fiber filter paper.

As per ASTM D 4627 standard, the rate of corrosion is graded from 1 to 10, where ten is highly corrosive, five represent medium corrosion and one stands for non-corrosive cutting fluids (ASTM D, 4627, 2012). After corrosion test, rusted filter paper with several concentrations of BCF and MO is shown in **Fig. 9(a-b)**. Results shows that the amount of rusting reduces with the increase in concentration of cutting fluids. For BCF less rusting was observed as compared to filter paper of MO for all concentrations. Breakeven point of 8 and 9 are exhibited by BCF and MO, respectively, where no further rust is observed by naked eyes. It confirms that the BCF has better anti-corrosion properties with respect to MO based cutting fluids.

Moreover, the chips weight loss was also measured and reported as shown in **Fig. 10**. It is observed that chips weight loss and rate of corrosion reduces with the increase in concentration of cutting fluids. This is attributed to anti-corrosion properties of cutting fluids that slow the reaction of oxygen and iron in its presence. Even though BCF and MO have different composition, they follow similar behaviour in case of chips weight loss after corrosion tests.

Storage Stability of Cutting Fluids (ASTM D 3707)

During machining, generated heat and friction is reduced with the help of cutting fluids in the form of emulsions. Therefore, storage stability of cutting fluid emulsions is one of the important parameter to select cutting fluid for particular application. Cutting fluid emulsions storage stability tests are performed in accordance with ASTM D 3707 standard (ASTM D, 3707, 2010). As

Fig. 9 Rusty filter paper after corrosion test with several concentration of (a) bio-cutting fluid and (b) mineral oil.

per the guidelines, 50 mL of cutting fluid emulsions with ten varying oil concentration (1:2–1:20, 1 part of oil for 2–20 part of water) for both BCF and MO were prepared and kept in glass graduated cylinder (**Fig. 11(a)**). For storage stability tests, prepared samples were kept inside convection oven for 48 h at $85 \pm 1^\circ\text{C}$. After test, samples were kept at room temperature for an hour. Afterwards, amount of separated water, oil and remaining emulsions were measured in glass graduated cylinder (**Fig. 11(b)**).

In accordance with ASTM D3707 standard, storage stability of the emulsion was assessed by measuring separated oil and water from intact emulsion after tests. After tests, amount of sample evaporated was considered as separated water. Amount of initial sample minus measured separated oil and separated water was considered as an intact emulsion after tests. **Figs. (12–14)** illustrates the effect of emulsion concentration on separated oil, separated water and remaining emulsions, respectively for BCF and MO after oven tests. The result shows that separation of oil increases with the increase in concentration of water in emulsions (**Fig. 12**) for both cutting fluids. However, in case of BCF, the amount of separated oil is less as compared to MO. Moreover, the amount of separated water reduces up to 1:16 emulsion concentration while afterwards it starts increasing for both cutting fluids (**Fig. 13**). In the similar way, the amount of remaining emulsion increases up to 1:16 emulsion concentration while afterwards it starts increasing for both cutting fluids (**Fig. 14**). However, in all cases, the amount of separated oil and separated water is less for BCF as well as the amount of remaining emulsion is high for BCF as compared to MO. The emulsion type and composition showing the least separation (most remaining emulsion) after oven test is considered as the most stable composition. Therefore, based on the measured parameters, the storage stability of 1:16 BCF emulsion composition is proved to be better among others.

Machining Experiments Using Cutting Fluids

Machining experiments are carried out using a lathe (Make: HMT[®], Model: NH 26) equipped with a tool holder (Make: Sandvik[®], Model: PTG NR 2525 M16) and tungsten carbide tool insert (Make: Sandvik[®], Model: TNMA 220412). Machining experiments are carried out at MQCF environment using sustainable BCF and MO. Cutting tool insert was TiN coated on flank face. This inserts were selected as during machining MQCF spray was only injected in-between workpiece and cutting tool rake face. AISI H-13 steel

were chosen as workpiece material due to its various applications and high average hardness (56 ± 2 HRC). Workpiece material has C 0.32%–0.4%, Mo 1.33%–1.4%, Cr 5.13%–5.25%, Si 1%, V 1% and Fe remaining. **Table 4** shows the machining conditions (Gajrani *et al.*, 2017b).

Fig. 15 illustrates machining experimental setup with MQCF technique. The average cutting and feed forces are measured using a Kistler® make piezoelectric quartz dynamometer (Model: 9272B). Mahr® make contact type surface profilometer was used to measure the workpiece surface roughness. All experiments are repeated thrice and average values are plotted.

Both BCF and MO are applied using MQCF technique for enhanced lubrication with minimum amount of cutting fluid during hard turning of AISI H-13 steel. Effect of both cutting fluid viscosity on the cutting and feed forces are illustrated in **Fig. 16(a-b)**.

Fig. 15 Tool-workpiece-mist interaction region during machining with minimum quantity cutting fluid technique.

Fig. 16 Effect of cutting fluid viscosity on cutting and feed forces.

Result shows that the performance of BCF is superior to that of MO in terms of both cutting and feed forces. This is attributed to better lubricating ability of BCF because of its high viscosity as compared to MO.

In general, low viscosity cutting fluids are preferred for better flow ability and cooling properties. However particularly with MQCF technique, cutting fluid lubricating property should dominate rather than its flow ability. The relation between cutting fluid viscosity and machining force is complex. Even though the flow ability of cutting fluid is compromised by higher viscosity cutting fluid but machining forces reduces. This is mainly because of MQCF technique. In this technique, cutting fluid is mixed with air and atomized in the form of mist/spray, which is directly focused in between tool-chip interface. Therefore, flow ability of cutting fluid is not that much important as compared to its viscosity which provides better lubrication. Apart from high viscosity, BCF has a better thermal property, thermal conductivity and specific heat capacity that also help in improving its machining performance (Gajrani *et al.*, 2017b).

The tool-chip interface coefficient of friction is calculated as follows (Ernst and Merchant, 1941):

$$\mu = \tan(\alpha) = \tan(\lambda + \tan^{-1}(F_f/F_c)) \quad (3)$$

where F_f and F_c represents the feed and cutting force, λ and α represents the friction and rake angle, respectively. The effect of both cutting fluid viscosity on the tool-chip interface coefficient of friction is illustrated in Fig. 17.

Result shows that the tool-chip interface coefficient of friction is less for machining with BCF as compared to MO. This is due to reduced total tool-chip contact length using BCF (Fig. 18) (Gajrani *et al.*, 2017b). In another study, similar behaviour was also observed during machining with green cutting fluid (Gajrani *et al.*, 2017c). Fig. 18(a-b) illustrates the tool rake face morphology showing tool-chip interface region after machining with BCF and MO using MQCF technique. Tool rake face after machining with MO shows severe adhered material from workpiece (Fig. 18(b)) (Gajrani *et al.*, 2017b). In contrast for tool rake face after machining with BCF, fewer workpiece adhered material was observed (Fig. 18(a)) (Gajrani *et al.*, 2017b). Fig. 18(c) shows the elemental composition of adhered material (Area A), which is similar to the composition of workpiece material (Fe in bulk). This evidence supports the adhesion of workpiece material on the tool rake face. Also, the overall tool-chip contact length is lower for the cutting tool after machining with BCF as compared to MO (Fig. 18(b)) (Gajrani *et al.*, 2017b). This is attributed due to high viscosity of BCF, which creates better lubricating film in between tool-chip interface and it does not allow chip material to slide directly over the cutting tool rake face for more length. Therefore, with increase in viscosity of cutting fluid, the tool-chip contact length decreases that lead to the reduction of friction force which ultimately lower friction coefficients.

Fig. 17 Effect of cutting fluid viscosity on tool-chip interface coefficient of friction.

Fig. 18 Tool rake face morphology showing tool-chip interface region after machining with (a) bio-cutting fluid, (b) mineral oil showing adhesion and abrasion wear and (c) elemental composition of adhered material (Area A, Fig. 18 a). Copyright [2017], Copyright holder [Elsevier].

Afterwards, the effect of both cutting fluid viscosity on the surface roughness is shown in **Fig. 19**. The result shows that workpiece surface roughness after machining with BCF is lower as compared to MO. This is attributed to lower machining forces with BCF due to which tool chatter also reduces. Thus, it leads to the better workpiece surface finish.

Fig. 19 Effect of cutting fluid viscosity on workpiece surface roughness.

Concluding Remarks

The physical, thermal, rheological, biodegradation, anti-corrosion and storage stability properties of sustainable BCF and petroleum-based MO are assessed and compared. Machining experiments were conducted with BCF and MO using MQCF technique. The salient findings are as follows:

- The flash point of BCF is higher as compared to MO that allows its use for high temperature hard machining.
- BCF exhibits less variation from Newtonian behaviour even at higher temperature. Also, its sensitivity to temperature is lower as compared to MO.
- As per *Standard methods 2005*, ultimate biodegradability of BCF and MO is found to be 96.67% and 18.32%, respectively.
- BCF showed corrosion breakpoint of 8; whereas MO exhibits corrosion breakpoint of 9 as per ASTM D 4627 standard.
- As per ASTM D 3707 standard, BCF shows more remaining emulsion as compared to MO after storage stability test.
- Sustainable BCF showed better machining performance as compared to MO in terms of cutting force, feed force, tool-chip interface coefficient of friction and surface roughness due to its high viscosity and better lubricating properties.

Sustainable Machining With Self-Lubricating Coated Mechanical Micro-Textured Cutting Tools

Kishor K Gajrani and Mamilla R Sankar, Indian Institute of Technology, Guwahati, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Main purposes of cutting fluids are to cool and lubricate machining region as well as to flush away the chips produced. Cutting fluids have various merits over dry machining. During machining, use of cutting fluids improves machined surface finish and reduces cutting tool wear. In general, cutting fluids also have anti-corrosion properties, which protect machined surfaces from corrosion. Cutting fluids also save power consumption by reducing the machining forces. In few applications, the associated costs of cutting fluids are higher than tool related costs (Astakhov, 2008). However, apart from merits, cutting fluid also possess various detrimental effects on the environment and health hazard to the operators (Gajrani and Sankar, 2017a).

Cutting fluid associated diseases to operators are mainly caused due to direct contact or inhalation of its fumes, which produces during machining. Dermatitis, skin irritation, folliculitis and allergic reaction are caused due to direct contact of cutting fluids. However, hypersensitivity pneumonitis, bronchitis and asthma are few examples of diseases caused due to inhalation of cutting fluids fumes (Sankar and Gajrani, 2017). Most of the chemicals present in petroleum-based cutting fluids are suspected carcinogens (Dixit *et al.*, 2012). Moreover, due to prolonged exposure to cutting fluids; machine and materials are also affected. For example, water-based cutting fluid emulsions cause corrosion and stains on machined surface.

Disposal of cutting fluids after its usage is a major concern. In general, waste cutting fluids are dumped either in water bodies or landfill. Thus, it can pollute groundwater, surface water as well as can cause soil contamination, which ultimately affects agriculture and contaminate food (Dixit *et al.*, 2012). Therefore, use of cutting fluids need to be minimized or eliminated.

Few researchers have reduced amount of cutting fluid usage by adopting minimum quantity cutting fluids (MQCF) (Gajrani *et al.*, 2017a). In MQCF, a combination of pressurized air is mixed with cutting fluids to form a mist, which is directly injected at the tool-chip interface to reduce heat and to lubricate sliding interface (Gajrani *et al.*, 2017b). However, due to mist nature of MQCF mixture, cutting fluid mix with atmospheric air and easily inhaled by operators working in its vicinity, which may lead to indirect diseases caused by cutting fluids. Thus, it is recommended to totally avoid usage of cutting fluids. Keeping in mind the safety of environment and operators, one of the viable solutions is dry machining (Sreejith and Ngoi, 2000).

Dry machining has several merits such as safety of operators and environments as well as no issue of cutting fluid disposal. However, alternatives to the function of cutting fluids need to explore to reduce heat from machining region and to lubricate tool-chip interface. Researchers have tried various different methods to reduce heat from machining zone such as the use of heat pipe (Jen *et al.*, 2002), internal cooling (Sanchez *et al.*, 2011), cryogenic cooling (Yildiz and Nalbant, 2008), thermoelectric refrigeration (Sreejith and Ngoi, 2000). Researchers have also tried to lubricate machining zone during dry machining using various techniques such as trilayer and multilayer hard coating of various substances on the surface of cutting tools (Kustas *et al.*, 1997; Koshy, 2008). One such technique to enhance tribological properties in-between tool-chip interface is to fabricate controlled surface textures on the rake of cutting tools (Gajrani *et al.*, 2016; Gajrani and Sankar, 2017b).

Controlled engineered modification of surfaces by fabricating micro to nano patterns using various techniques is known as surface textures. Surface textures have the ability to reduce friction between two sliding pairs due to which it is getting wide attention. Optimized textures can improve various functions of surfaces. Engineered surface textures have the variety of applications in industries such as medical implants, to create hydrophobic surfaces, microfluidics, MEMS components, piston rings, bearings, acoustics, etc., (Coblas *et al.*, 2015). Micro-textures can be fabricated using a variety of techniques including both conventional and unconventional methods in varying geometry, shape and size (micrometre to nanometre level). Unconventional texturing methods such as laser (Li *et al.*, 2014), electrical discharge machining (Wenlong *et al.*, 2011), focused ion beam (Kawasegi *et al.*, 2017), etc. have been employed to fabricate micro-textures on the number of various previous studies. In past decade, surface textures are introduced on the tool rake and flank surface to reduce frictional heating at the machining region.

Due to the presence of micro-textures, the actual contact length of tool-chip interface reduces, which in turn reduces sliding friction (Jianxin *et al.*, 2009). Another study reported lesser tool-chip contact length up to 30% due to the presence of micro-textures (Lei *et al.*, 2009). This also favours lesser workpiece material adhesion on the surface of the cutting tool, which leads to stabilize the built-up edge formation (Kummel *et al.*, 2015). Sugihara and Enomoto (2012) have also reported the reduction in adhesion of aluminium workpiece on the tool surface due to the presence of nano/micro textures. Sharma and Pandey (2016) have filled surface textures using calcium fluoride (CaF₂) solid lubricant. Result shows that CaF₂ was able to reduce friction heat generation from machining zone. Deng *et al.* (2013) carried out machining experiment using molybdenum disulphide (MoS₂) coated micro-textured cutting tools and it was found that cutting temperature and cutting force was reduced as compared to machining with convention tool.

As discussed above, surface textured cutting tools have several benefits; however, in most of the studies, thermal-based texturing techniques have been used to fabricate micro-textures. There are several issues with thermal-based texturing techniques such as the formation of recast layer, formation of heat affected zone, development of thermal stress and formation of cracks (Gajrani *et al.*, 2018b).

Fig. 1 Micrograph and corresponding 3-d surface profile of (a) single micro-groove fabricated using CO₂ laser and (b) single micro-groove fabricated using scratch tester. Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". *Tribology International* 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

These issues can be eliminated by fabricating surface textures using conventional mechanical techniques. Mechanical micro-textures (MμTs) can be fabricated using the scratch tester, Rockwell hardness tester, nano-indenter and Vicker hardness tester. A typical example of fabricated micro-groove using CO₂ laser and scratch tester is shown in Fig. 1 (Gajrani *et al.*, 2018a). MμTs are easy to fabricate, accurate, repetitive, less time consuming and free from heat affected zone, recast layer as well as thermal stresses.

In this work, three different geometric types of MμT cutting tools were fabricated using mechanical texturing technique. Afterwards, another set of MμT cutting tools were coated using MoS₂ solid lubricant. Hard machining experiments were conducted using six different type of cutting tools while machining of hardened AISI H-13 steel. Machining performance of those cutting tool was compared in terms of machining region temperature, machining forces, coefficient of friction (COF), machined surface finish and tool surface morphology. For comparison purpose, hard machining experiments were also conducted using conventional untextured (UT) cutting tool.

Selecting Area for Texturing and Fabrication of Micro-Textures on the Cutting Tool Rake Face

Preliminary experiments were conducted using UT tool for 15 minutes to select area for texturing on the cutting tool rake face ($f=0.28$ mm/rev, $v=125$ m/min, $\alpha=0.5$ mm). Fig. 2(a) illustrates maximum affected UT tool rake face morphology after preliminary experimentation (Gajrani *et al.*, 2018a). Also, UT rake face was identified for abrasion and adhesion worn areas as well as notch wear as shown in Fig. 2(b-c) (Gajrani *et al.*, 2018a). Texturing area was selected such that it can encompass abrasion and adhesion worn areas with adequate margin as shown in Fig. 2(d) (Gajrani *et al.*, 2018a).

Vicker hardness tester and Ducom[®] make scratch tester (Model: TR-101) were used to fabricate MμTs on the tungsten carbide cutting tool rake face. Three different type of cutting tools were fabricated named VT, PT and PDT cutting tools. VT cutting tools have an array of micro-dimple on its rake face fabricated using Vicker hardness tester. PT and PDT cutting tools have an array of

Experimental Design

An efficient technique for determining the correlation between control parameters and output parameters by conducting least number of experiments is known as experimental design or design of experiments. One such technique is central composite rotatable design (CCRD). As per CCRD, for n number of inputs, the total numbers of experiments are $2^n + 2n + \text{central run}$ (Cochran and Cox, 1968). For two control parameter (feed and cutting speed) with five central runs (for better repeatability and assessment), $4 + 4 + 5 = 13$ experiments are required with each type of cutting tool. Feed and cutting speeds were selected based on the preliminary experiments. Depth of cut (0.5 mm) was kept constant during experiments. **Table 1** shows the original and coded value of control parameters (Gajrani et al., 2018a).

Table 1 Machining input parameters actual and CCRD coded values

CCRD coded values	Cutting speed (m/min)	Feed (mm/rev)
−1.414	55	0.04
−1.000	65	0.08
0.000	90	0.16
1.000	115	0.24

Materials and Machining Experiments

Hardened AISI H-13 steel was chosen as workpiece material due to various applications such as stamping dies, hot shear blades, forging dies, extrusion tools, casting tools, pressure die, plastic moulds, etc. The workpiece was in the form of a cylindrical rod having 250 mm length and 50 mm diameter with the average hardness of 56 ± 2 HRC. The chemical composition of hardened AISI H-13 steel is Mo 1.33%–1.4%, V 1%, Si 1%, Cr 5.13%–5.25%, C 0.32%–0.4% and Fe remaining. Tungsten carbide Sandvik Coromant[®] insert (Model: TNMA220412) was selected as cutting tool insert along with PTG NR 2525 M 22 tool holder. Table 2 illustrates the workpiece and cutting tool inserts material properties (Gajrani *et al.*, 2018a). Commercial tool holder has nose radius (r_n) of 1.2 mm, angle of approach (K_r) of 9°, inclination angle (λ_s) of −6°, clearance angle (α_o) of 0° and rake angle (γ_o) of −6°. Machining experiments were carried out with all six uncoated and MoS₂ coated MμT cutting tools. Machining with UT tool was also conducted for reference and comparison purpose. Kistler[®] dynamometer (Model: 9272 B) and Infratech[®] thermal infrared camera (Model: VARIOCAM hr-400) was used to measure machining force and temperature of the machining region, respectively. Afterwards, Zeiss[®] optical microscope (Model: AxioCam MRc) and Zeiss[®] field emission scanning electron microscopy (FESEM, Model: Sigma) were used to characterized surface morphologies of worn out cutting tool rake face. Overview of machining experimental setup with the dynamometer, tool post, workpiece and magnified view of micro-textured tool insert is illustrated in Fig. 6 (Gajrani *et al.*, 2018a).

Temperature of Machining Region

Tool life and machined surface finish highly depends upon the temperature of machining region. Thermal infrared camera was used to measure the temperature of machining region. Experiments were carried out in accordance with CCRD. Plan of experiments and output temperature of machining region with various cutting tools are illustrated in Table 3 (Gajrani *et al.*, 2018a).

As per CCRD, the obtained correlations for the temperature of machining region in terms of control parameters for various cutting tools are as follows (Gajrani *et al.*, 2018a):

$$T_{PDT-M} = -417.81 + 2814.03f + 7.418v + 3.642vf - 5709.36v^2 - 0.03512f^2 \quad (1a)$$

$$T_{PT-M} = -441.766 + 2952.04f + 8.33v + 3.522vf - 6001.79v^2 - 0.0374f^2 \quad (1b)$$

$$T_{VT-M} = -496.375 + 3271.73f + 9.18v + 3.41vf - 6451.13v^2 - 0.0401f^2 \quad (1c)$$

where f and v are the feed (mm/rev) and cutting speed (mm/rev), respectively. Machining region temperature (T) subscript represents the cutting tool type.

Analysis of variance (ANOVA) was carried out for the temperature of machining region while PDT-M self-lubricating tool being used (Table 4; Gajrani *et al.*, 2018a). From the table, it was observed that the temperature of machining region was mostly influenced by cutting speed terms (B and B^2), which have around 64.72% contribution. However, feed terms (A and A^2) have around 35.1% influences on it. ANOVA was also carried out with all other cutting tools and coefficient of determination (R^2) was more than 0.92.

Influence of cutting speed on the machining region temperature is illustrated in Fig. 7 (Gajrani *et al.*, 2018a). It is observed that machining region temperature is greatly affected by cutting speed. With the increase in cutting speed increases, the material removal rate (MRR) also increases. Therefore, the per unit interaction time in-between tool-workpiece is less for the same amount of MRR, which results in rising temperature as shown in Fig. 7 (Gajrani *et al.*, 2018a).

Machining region temperature during machining with UT tool is high among all. This is attributed to higher tool-chip contact length on the rake face of the tool. Higher contact length results in the high frictional force that leads to rise in temperature. However, during machining with M μ T tools, because of the presence of an array of micro-textures on the cutting tool rake face, the actual tool-chip contact length reduces. Lesser contact length causes less friction force, which in terms reduces machining region temperature as compared to UT cutting tools. Actual tool-chip contact length is given below:

$$l_f' = l_f - n.d \quad (2)$$

where d denotes the average width of M μ T, n represents the number of M μ T in-between contact length, l_f represents apparent tool-chip contact length and l_f' denotes real tool-chip contact length.

In case of MoS₂ coated M μ T tools, when machined chips travel on the cutting tool rake face, temperature rises, which causes to semi-solidifying solid lubricant. Further, MoS₂ sticks on the back face of machined chips and slides over the tool rake face in chip flow direction. Released MoS₂ from M μ T spread over the tool rake face and create a thin self-lubricating film.

In general, the shear strength of MoS₂ is in the range of 30–35 MPa, whereas tungsten carbide shear strength is about 700–800 MPa. Therefore, due to the presence of MoS₂ solid lubricant layers in-between tool-chip interface, the overall frictional force reduces, which further leads to the reduction in temperature. Therefore, in case of machining with MoS₂ coated M μ T tools, the machining region temperature is less as compared to M μ T and UT tools. Fig. 8 shows schematic representation of the tool-chip interface for UT tool and M μ T tool showing plucked out tungsten grains and iron-molybdenum sulphide-bridge formation, respectively that helps in the formation of MoS₂ self-lubricating film (Gajrani *et al.*, 2018a). Fig. 9 illustrates the thermal micrograph of machining region temperature during machining with UT, PDT and PDT-M tools (Gajrani *et al.*, 2018a).

Machining Forces

As per CCRD, the empirical models of feed force and cutting force for various different cutting tools are as follows:

$$F_{NT} = -10.73 + 663.99f + 1.018v - 0.79vf - 699.61f^2 - 0.006v^2 \quad (3a)$$

$$F_{PT} = 11.01 + 658.89f + 0.62v - 1.08vf - 665.30f^2 - 0.004v^2 \quad (3b)$$

$$F_{PDT} = 35.74 + 649.27f - 0.25v - 1.58vf - 415.84f^2 + 0.0016v^2 \quad (3c)$$

$$F_{cPT-M} = 308.17 + 2284.53f - 6.17v - 9.96vf + 325.61f^2 + 0.03v^2 \quad (4e)$$

$$F_{cPDT-M} = 264.46 + 2301.38f - 5.65v - 10.295vf + 484.361f^2 + 0.03v^2 \quad (4f)$$

$$F_{cCT} = 529.18 + 1302.57f - 7.45v - 2.48vf + 644.81f^2 + 0.03v^2 \quad (4g)$$

where the F_f and F_c represent feed force and cutting force and the subscripts show the tool type.

The influence of cutting speed on the feed force and cutting force with different types of tools is illustrated in Figs. 10 and 11, respectively (Gajrani *et al.*, 2018a). With the increase in cutting speed, keeping the constant interaction time between workpiece and tool, the MRR increases. Increase in MRR causes rise in primary and secondary shear zone temperatures. As the workpiece

Fig. 10 Influence of cutting speed on feed force. Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

Fig. 11 Influence of cutting speed on cutting force. Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

thermal conductivity is high, the temperature ahead of tool-workpiece interaction region also increases. This, preheating of the machined zone is known as thermal softening of the workpiece, which helps to decrease workpiece flow stress leading towards the reduction of feed force and cutting forces with increase in cutting speed. Results show that the feed force and cutting force while machining with uncoated and MoS₂ coated M μ T tools is lower as compared to UT tool. Two main reasons explain this behaviour. First, while machining with M μ T tools, the actual contact length reduces leading towards the lesser frictional force. Thus, machining force reduces. In case of MoS₂ coated M μ T tools, the formation of self-lubricating film in-between sliding interfaces is another reason (Gajrani *et al.*, 2018c).

Tool-Chip Interface Coefficient of Friction

COF was calculated using the concept of Merchant circle with experimental feed force and cutting force data. As per Ernst and Merchant (1941), tool-chip interface COF is as follows:

$$\mu = \frac{F_c \sin \alpha + F_f \cos \alpha}{F_c \cos \alpha - F_f \sin \alpha} \quad (5)$$

where μ represents the COF and α denotes the cutting tool rake angle.

The influence of cutting speed on the tool-chip interface COF for various tools is illustrated in Fig. 12 Gajrani *et al.* (2018a). As discussed above in the previous section, due to the presence of M μ T on the tool rake face, the contact length reduces. Thus, frictional force reduces, which leads to reduction in coefficient of friction. Moreover, in case of MoS₂ coated M μ T tools, the presence of MoS₂ in-between tool-chip interfaces further reduces the coefficient of friction.

MoS₂ coated PDT cutting tool perform best among all uncoated M μ T and UT tools concerning machining region temperature, cutting force, feed force and tool-chip interface COF. This is attributed to the lowest tool-chip contact length with PDT tool. Fig. 13 illustrates the typical representation of chip flow direction over various uncoated M μ T tools (Gajrani *et al.*, 2018a). For constant feed (0.16 mm/rev), cutting speed (90 m/min) and depth of cut (0.5 mm), the experimentally measured chip flow direction from tool principal cutting edge is at 18°. From Eq. 2, actual contact length depends on n and chip flow direction. For this particular case, keeping chip-flow direction constant as shown in Fig. 13, n will be maximum for PDT cutting tool ($n_{VT} < n_{PT} < n_{PDT}$). Therefore,

"Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

contact length is least for PDT tools. Thus, PDT performs better among all uncoated M μ T and UT tools. Further, PDT-M tool performs best among all tools due to least contact length as well as the formation of MoS₂ self-lubricating film on the tool rake face.

Tool Rake Face Morphology

Tool rake face morphology after machining is an important parameter to understand the performance of cutting tool at the particular condition. After 15 min of machining ($f=0.16$ mm/rev, $v=90$ m/min, $a_w=0.5$ mm), cutting tool rake face surface morphology was characterized using FESEM. Corresponding elemental maps and elemental composition micrographs were also characterized using elemental dispersive spectroscopy (EDS). UT tool rake face surface morphology is illustrated in Fig. 14 (Gajrani *et al.*, 2018a).

As discussed in previous sections, machining region temperature is high while machining with UT cutting tool, which also causes rise in workpiece temperature. Thus, due to preheating of workpiece material and continuous chip flow over the cutting tool rake face, adhesion wear is predominant. Due to repetitive tool adhesion on the back side of the machined chips, tungsten carbide material plucks out from the UT cutting tool that leads to its catastrophic failure (Fig. 14(a-b); Gajrani *et al.*, 2018a). Fig. 14(c) illustrates the UT rake face fractured surface and its interface with parent tool (Gajrani *et al.*, 2018a). Fig. 14(d) shows the tungsten carbide tool material shredding from the UT tool rake face due to tool adhesion on the back side of the machined chips (Gajrani *et al.*, 2018a).

After 15 minutes of machining ($f=0.16$ mm/rev, $v=90$ m/min, $a_w=0.5$ mm), VT-M, PT-M and PDT-M M μ T tool rake face surface morphology, corresponding iron (Fe), molybdenum (Mo) as well as sulphur (S) elemental maps and elemental composition is shown in Figs. 15–17, respectively (Gajrani *et al.*, 2018a). Worn out VT-M tool rake face morphology is illustrated in Fig. 15(a) (Gajrani *et al.*, 2018a). Corresponding to VT-M tool rake face, Fe, Mo and S elemental maps are shown in Fig. 15(b–d) (Gajrani *et al.*, 2018a). Elemental map of Fe confirms the workpiece material adhesion on the VT-M tool rake face. Further, elemental maps of Mo and S shows that MoS₂ solid lubricant was able to spread out over the cutting tool rake face and has created a thin self-lubricating film. Further, elemental composition analysis of point U and V (points in Fig. 15(a)) is shown in Fig. 15(e–f) (Gajrani *et al.*, 2018a). Point U is chosen near the vicinity of VT-M tool cutting edge while point V is chosen on the M μ T. From the elemental analysis, it is confirmed that Fe weight percentage is high near the cutting edge. This is attributed to predominant adhesive wear near tool cutting edge.

Similar to VT-M tool, surface morphology, elemental maps and elemental composition analysis of PT-M tool as well as PDT-M tool rake face confirms the formation of the thin self-lubricating film as shown in Figs. 16 and 17, respectively (Gajrani *et al.*, 2018a).

Fig. 14 After 15 minutes of machining: (a) Rake face micrograph of untextured tool, (b) tool catastrophic failure, (c) tool fractured surface and (d) tungsten carbide material shredding from parent tool. Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". *Tribology International* 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

Fig. 15 After 15 minutes of machining: (a) Rake face micrograph of Vickers textured self-lubricating tool, (b) corresponding elemental map showing iron distribution, (c) corresponding elemental map showing molybdenum distribution, (b) corresponding elemental map showing sulphur distribution, (e) elemental composition corresponding to point U and (f) elemental composition corresponding to point V. ; Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

Fig. 16 After 15 minutes of machining: (a) Rake face micrograph of parallel textured self-lubricating tool, (b) corresponding elemental map showing iron distribution, (c) corresponding elemental map showing molybdenum distribution, (b) corresponding elemental map showing sulphur distribution, (e) elemental composition corresponding to point W and (f) elemental composition corresponding to point X. ; Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

Fig. 17 After 15 minutes of machining: (a) Rake face micrograph of perpendicular textured self-lubricating tool, (b) corresponding elemental map showing iron distribution, (c) corresponding elemental map showing molybdenum distribution, (b) corresponding elemental map showing sulphur distribution, (e) elemental composition corresponding to point Y and (f) elemental composition corresponding to point Z ; Reproduced from Gajrani, K.K., Suresh, S., Sankar, M.R., 2018a. "Environmental friendly hard machining performance of uncoated and MoS₂ coated mechanical micro-textured tungsten carbide cutting tools". Tribology International 125, 141–155. doi:10.1016/j.triboint.2018.04.031.

However, regarding PDT-M tool, the tool-chip contact area is smaller as compared to PT-M tool. Further, workpiece material adhesion is lesser as compared to other cutting self-lubricating tools. Elemental maps of Mo and S illustrates uniform lubricating film formation. Therefore, it can be confirmed that PDT-M M μ T cutting tool performs best among all other cutting tools in terms of machining region temperature, cutting force, feed force, tool-chip interface COF and tool rake face morphology.

Concluding Remarks

M μ T cutting tools having three different geometries were fabricated for machining. Another set of M μ T cutting tools were coated using MoS₂ solid lubricants. Hard machining experiments were conducted using uncoated, coated M μ T and UT cutting tools. Machining performance was compared and their salient findings are as follows:

- (1) Uncoated and MoS₂ coated self-lubricating tools reduce machining region temperature, cutting force, feed force and tool-chip interface COF as compared to UT tools.
- (2) MoS₂ coated PDT-M tool performs best among all. It is due to the least tool-chip contact length and formation of MoS₂ self-lubricating film over the cutting tool rake face.
- (3) As compared to UT tools, PDT-M tool reduces tool-chip interface COF in the range of 11.73%–17.42%.

Introduction

Sustainability issues are a major concern in our modern life. Energy and materials are important aspects to be considered. The current need for enhancement in energy efficiency technologies is driven by an urgency of maximizing the moderate global energy efficiency to match the increasing demand. It has been shown ([Exxonmobil's, 2017](#); [International Energy Agency, World Energy Outlook, 2016](#)) that improvements of energy efficiencies resulted in a significant cut to the global energy demand by two-thirds over the past decades, as shown in [Fig. 1](#). Many approaches could be adopted for energy efficiency enhancement, amongst which energy conversion and storage are the least developed. The main reasons for this may be due to lack of appropriate economic, sustainable and eco-friendly materials.

Sustainable materials for waste energy recovery and conversion are currently exploited for new trending applications. Fields of solar energy conversion into thermal energy and waste heat recovery/electrical energy generation are amongst the hot topics for new environmentally friendly and sustainable sources of green energy. Most of the research efforts are conducted towards developing new sustainable materials for energy conversion applications. Polymer base materials have recently proven to be excellent candidates and good alternatives for other metallic and ceramic-based energy conversion materials.

Energy Conversion Applications

Energy conversion from one form to another has been known through all human ages. This work focuses on conversion of solar energy and waste heat to useful energy forms for modern applications. Solar energy is harvested by photovoltaic materials (for electric energy generation) and selective absorber materials (for thermal energy generation). The idea of converting waste energy to useful heat or energy fits well within sustainability requirements. Waste heat is defined as the generated heat as a by-product of daily and industrial process ([Viklund and Johansson, 2014](#)). Different technologies and materials have been developed over the past decades to harvest as much as possible of the waste heat considering it as a primary source of energy. Thermoelectric generation, solar thermal collectors, phase change materials, thermoacoustic materials, organic rankine cycles are the most trending technologies for waste heat recovery ([Anon, 2015](#)). The sources of waste heat have extended to include any activity, which results a temperature 10 k higher than the room temperature, such as human activities, vehicles exhausting systems, electrical utilities, etc. However, this small temperature difference is only compatible with the low temperature energy conversion/storage polymeric based materials. Though metal based and ceramic based materials have reached a mature stage of development relative to energy conversion and storage applications, polymeric based materials have great options for expanding the range of applications due to their large sensitivity over a narrow range of temperature difference.

Materials Requirements for Energy Conversion

The choice of a material for energy conversion applications is governed by a set of its physical properties; mainly electrical, thermal and optical properties. The basics and fundamentals of these properties for different types of engineering material is discussed in this section.

Electrical Properties of Materials

The electrical or electronic properties of materials describe the response of the material in the presence of an applied electric field. Although electricity concepts can seem complicated, an electric current is just the flow of electrons from one atom to the other and this flow is dependent on the type and the structure of the material. Solid metals are characterized by their metallic bonds, where the atoms form a tightly packed structure with a positive cationic core soaked in a negative loose electron cloud characterized by the delocalized nature of the valence electrons, which makes metals excellent conductors of electricity. Ceramics are characterized by ionic bonding, which usually forms between metals and nonmetals. The ionic bond is characterized by electrical neutrality and the electrons are firmly kept inside the bond, which makes ceramics excellent insulators. Generally, in polymers and nonmetals, which are considered to be insulators too, the electrons are held tightly to the nucleus preventing their free movement as they are usually shared in the covalent bond ([Smith and Hashemi, 2011a](#)).

The transistors were invented in 1947–1948 at Bell Telephone laboratories; which opened a new field of technology that led to advancement in electronic devices and machines. All the computers, mobiles and other electronic devices contain thousands but millions of different types of transistors. This invention was possible because of the semiconducting behaviour of certain metals

and alloys. What makes semiconductors so special is the ability of altering their conductivity through adding impurities in a process called doping. Semiconductors with excess electrons are called n-type semiconductors and the ones with shortage in electrons or more specifically the ones with excess holes are called p-type semiconductors. Different combinations and configurations of n-type and p-type semiconductors result in numerous electronic devices starting from diodes and transistors (Hu, 2009). Another important aspect of semiconductors that distinguishes them is that they have an almost empty conduction band and an almost filled valence band, which are separated by a specific band gap. When an electron from the valence band receives in any way an amount of energy bigger than the energy of the band gap it will be excited to the conduction band which will in return increase the conductivity. In fact, this special characteristic is utilized in lots of interesting technologies such as solar cells and photoconductors. Examples of semiconducting metals are the group-4 elements with silicon and germanium being the most famous. Group3-Group5 compounds, such as GaAs, are also famous for their semiconducting properties. Actually, there are also a number of famous ceramics that are considered semiconductors such as SiO_2 , TiO_2 and ZnO_2 (Hu, 2009; Ross, 2006). Indeed, each semiconductor is characterized by its own band gap energy, carriers' distributions and the electrons and holes mobilities; which set the basis for the comparison between them in a theoretical level for any application. However, when it comes to real world devices and applications, availability, costs and environmental effects are also considered.

Despite the fundamental fact that metals are good conductors and far better than polymers, this idea changed when Hideki Shirakawa pioneered the field of conductive polymers. In 1977, Shirakawa, MacDiarmid and Heeger, who shared the noble prize in chemistry in 2000, discovered that oxidation with chlorine or bromine vapor raised the conductivity of polyacetylene films by a factor of 10^9 to reach 10^5 Siemens per meter, which means that the conductivity of polyacetylene increased to a level that approached that of copper (Shirakawa *et al.*, 1977). Although, metals are the best conductors known, they are associated with many problems such as the costs and environmental impacts of both mining and preparation stages. Therefore, conductive polymers has introduced a functionally available alternative and consequently the research on them has increased exponentially in a pursuit to understand their full potentials and to implement them in the development of technology.

In general, the electrons in polymers are not delocalized like in metals. However, the conducting organics are distinguished by their alternating single and double bonds that forms a conjugated structure as shown in Fig. 2. These molecules can be either polymers or smaller molecules that conduct electricity through delocalized pi-electrons, which can move easily within a molecule and can tunnel between molecules. This kind of conduction is called hopping and relies on the match between the highest occupied molecular orbitals HOMO and the lowest unoccupied molecular orbitals LUMO in the adjacent molecules. In fact, HOMO and LUMO are the analogies to the valence band and the conduction band respectively and they are also separated by a band gap (Solymar *et al.*, 2014).

The conjugated structure is not enough to guarantee a conductive polymer, as it also depends on the doping level. Dopants act as donors or acceptors to provide electrons or holes, respectively. An undoped conjugated polymer is considered to be an insulator. With more doping, the conjugated polymer becomes an organic semiconductor and finally with a large extent of doping it can reach remarkably high values of conductivity. In fact, organic semiconductors are progressively utilized in a wide range of technologies. What makes them attractive is that their band gaps can be tuned by adjusting the structure of the molecules and then they can be engineered to meet specific demands (Ross, 2006; Saleh and Teich, 2007).

In conducting polymers, the carriers move via hopping as they are localized to some extent. In fact, the carriers are present in the form of excitons, where an exciton is the bound state of an electron and a hole attached to each other by electrostatic force (Solymar *et al.*, 2014). Excitons diffuse in the material but they do not drift and they won't convey current till they split to separate

Fig. 1 Energy consumption with/without efficiency enhancement. Reproduced from Exxonmobil's, 2017. Outlook for energy: A view to 2040.

Fig. 2 Conjugated structure of conducting polymers. Reproduced from Ross, C., 2006. 3.15 electrical, optical & magnetic materials and devices. Fall 2006. Massachusetts Institute of Technology: MIT OpenCourseWare, License: Creative Commons BY-NC-SA. Available at: <https://ocw.mit.edu>.

electrons and holes by strong electric fields. Therefore, the carrier mobilities in most organic materials are typically low which results in apparent slow responses in the devices they are used in. For instance, the crystalline organic semiconductors with the highest mobilities can reach the 0.1–20 cm²/V·s range (Coropceanu *et al.*, 2007), which is very small compared to semiconductors such as silicon with an electron mobility of about 1500 cm²/V·s and a hole mobility of around 450 cm²/V·s (Ross, 2006).

In contrast, there are certain organic materials, graphene and carbon nanotubes being the most well-known, where carriers reach very high mobilities and thus are characterized by very high electrical conductivity. Graphene is an extended sheet of carbon that forms a 2D crystal, which is the first of its kind to be observed in science. Through this 2D crystal, electrons and holes can move freely as the delocalized π -orbital extends over the whole sheet. Carbon nanotubes are just rolled graphene sheets, which have very interesting technological applications. One interesting prospective application of graphene is to use a few nanometres graphene strip to replace the 50 nm electrical channels of silicon in transistors (Ross, 2006; Fuchs and Goerbig, 2008).

Optical Properties of Materials

Photovoltaics, LEDs and transmitting signals through optical fibres are all high technologies that depend on the optical properties of materials. The optical properties of materials are the set of characteristics that define the material's response to electromagnetic radiation including: colour, absorbance, transmission reflection and luminosity. Electromagnetic radiation, along with its wave like characteristics, consists of photons, which are packets of energy that can behave like particles. Optical properties are concerned in particular with the visible light, which extends from about 0.4–0.75 μ m in the electromagnetic spectrum (Smith and Hashemi, 2011b).

Metals are opaque to the radiation from the middle of ultraviolet radiation to the low energy radiation. Therefore, they are opaque to visible light, which indicates that all the visible light photons are absorbed by metals. Absorption happens when a photon excites an electron from the conduction band to the valence band and this happens when the incident photon has equal or higher energy than the band gap. However, this doesn't apply on high frequency photons. Naturally, this gives the impression that metals are dark black. However, energized electron falls back to their equilibrium original state by emitting a photon with the same wavelength it absorbed making it reflective and the distribution of these wavelengths gives the metal its colour. On the other hand, nonmetallic materials can be transparent, where the characteristic colour of a transparent surface is determined by the distribution of wavelengths of the non-absorbed light radiation that is transmitted through the material (Callister and Rethwisch, 2015a).

Photoconductivity is the electrical conductivity that rises from the increased number of electrons that are induced and excited by photons absorption in semiconducting materials. Electroluminescence is the emission of light due to the recombination between electrons and holes, which occur in light-emitting diodes (LEDs). In fact, the reverse of LEDs are solar cells where sunlight is converted to electrical current (Callister and Rethwisch, 2015a). The elemental semiconductors, semiconductor compounds and semiconductor ceramics show significant electrical and optical properties, however, they are difficult to handle and many of them show considerable environmental issues and undeniable toxicity. For example, according to CES EduPack 2018, 2018 Gallium requires appreciable care in handling, Indium compounds are highly toxic and Tin is carcinogenic (CES EduPack 2018, 2018).

Organic photovoltaics and LEDs have gained wide attention lately. When an organic semiconductor absorbs a photon, an exciton is classically formed, which can be split apart by an electric field, causing the electrons and holes to move in different directions away from each other's. A bilayer structure is needed to make an organic photovoltaic where holes are transported in a p-type layer, and electrons are transported in an n-type layer. In the case of an organic LED, electrons and holes are injected from opposing electrodes. Holes are injected by a high work function electrode, while electrons are injected by a low work function electrode. These electrons and holes recombine via excitons by emitting photons. Excitons exist in two forms according to their spin either singlets where the electron and hole have opposite spin or triplets where the electron and hole have the same spin. For every singlet produced, three triplets are formed. Actually, in LED only singlets contribute to photon formation, which means that just quarter of the carriers injected into organic materials can generate photons (Solyman *et al.*, 2014).

Thermal Properties of Materials

Thermal properties refer to the response of a material to the application of heat represented mainly by heat capacity, thermal expansion and thermal conductivity. **Table 1** presents typical thermal properties for some well-known engineering materials where the great differences between the thermal properties according to material type is evident (Callister and Rethwisch, 2015b).

Heat capacity is one of the important properties that qualify the material for energy conversion or storage applications. When a solid material is heated, it experiences a rise in temperature indicating absorption of energy. Heat capacity is a property that represents the material's ability to store thermal energy by the absorption of heat from the surroundings. Therefore, it represents the amount of energy needed to cause a unit temperature rise.

The Specific heat expresses the heat capacity per unit mass. Heat capacity is expressed in two ways based on maintaining either the specimen volume or the pressure constant but the difference is very insignificant for most solid materials at and below room temperature. Indeed, the energy is mainly absorbed by the increase of the vibrational energy of atoms along with the increase of the kinetic energy and the randomization of the electron spin in some special cases. Exchange of electrons is very limited in covalent bonds compared to metallic bonds. Consequently, polymers show the highest heat capacity as they are covalently bonded, followed by ceramics then metals (Callister and Rethwisch, 2015b).

Transport of thermal energy may be caused by the migration of free electrons and lattice vibrational waves. Phonons are considered to be the lattice vibration quanta. The electrons role to conduction heat transfer dominates in pure metals, while the contribution of phonons dominates in semiconductors and non-conductors (Incropera et al., 2017). The transport of heat energy by phonons is not as effective as free electrons due to the very efficient scattering of phonons by lattice imperfections

Fig. 3 Thermal conductivity vs specific heat capacity. Produced using CES EduPack 2018, 2018. Cambridge: Granta.

(Callister and Rethwisch, 2015b). The thermal conductivity is a property that represents the ability to conduct heat. In fact, the thermal conductivity is the proportionality constant between the heat flux and the temperature gradient along the direction of flow in steady-state heat transfer. The large numbers of free electrons and their efficiency to transport thermal energy in pure metals make them efficient thermal conductors. However, ceramics and polymers have low thermal conductivity due to phonon conduction domination and the low concentration of free electrons (Callister and Rethwisch, 2015b; Cengel, 2002). Crystalline solids and semi-conductors show high heat conductivity but poor electrical conductivity (Cengel, 2002). For thin films, the thermal conductivity is the lowest in the thin direction due to the effect of the physical boundaries (Incropera *et al.*, 2017).

Although polymers have high specific heat values, they are poor thermal conductors. In contrast, metals are efficient thermal conductors but have poor to modest specific heat values while ceramics shows modesty and moderation in both properties relative to metals and polymers. A graph between thermal conductivity and specific heat values is generated by CES EduPack and is shown in Fig. 3 (CES EduPack 2018, 2018). This raises the need for the thermal diffusivity property, which represents the ratio of thermal conductivity of the material to the heat stored per unit volume and measures the capability of conducting thermal energy relative to storing it. Therefore, materials of large thermal diffusivity such as metals reach equilibrium conditions in shorter period than materials with small thermal diffusivity as they respond quickly to thermal variations (Incropera *et al.*, 2017; Cengel, 2002).

Heating solid materials causes them to expand. Thermal expansion is the constant of proportionality between relative change in length to the temperature change. In fact, the increase in the average interatomic separation causes thermal expansion which is a result of the uneven nature of the potential energy versus the trough of the interatomic spacing curve. Therefore, the low coefficient of thermal expansion indicates a large interatomic bonding energy and vice versa. The values of thermal expansion for polymers are typically higher than metals and metals have higher thermal expansion coefficients than ceramic materials. Therefore, energy absorbance increases the interatomic distance in polymers rather than raising the temperature. Actually, Linear and branched polymers have higher thermal expansion coefficients than polymers with intercrossing (Callister and Rethwisch, 2015b). When the non-crystalline solids reach the glass temperature, it undergoes a transition to very viscous liquid (Ashby *et al.*, 2007). Table 2 shows a summary of the variation among the thermal properties of metals, polymers and ceramics.

The relation between thermal and electrical conductivity properties is behind the thermoelectric devices whose efficiency is measured by the figure of merit (ZT) which is a ratio between the electric conductivity to the thermal conductivity (Moriarty *et al.*, 2012). A graph between electrical resistivity and thermal conductivity is generated by CES EduPack and is shown in Fig. 4 (CES EduPack 2018, 2018). Therefore, for proper thermoelectric device, a material with low thermal conductivity and low electrical resistivity is needed. In other words, the materials which exist to the lower left of the graph in Fig. 4. Polymers have low thermal conductivity but high electrical resistivity while conductive polymers have low electrical resistivity, which makes them prospective candidates for thermoelectric devices.

Materials Requirements for Sustainability

Significant work has been conducted by Cambridge University, Materials research Society (MRS), the Metals Society (TMS) and European Union on defining sustainability challenges and concepts related to materials development and consumption (Allwood, 2012; Green *et al.*, 2012; Ashby, 2012). Sustainability concepts include Zero emission, industrial environmental sustainability, legislation, economics, sustainable technologies, renewable energy resources and energy efficiency of the technology processes.

Table 2 Thermal properties of metals, polymers and ceramics

	<i>Metals</i>	<i>Polymers</i>	<i>Ceramics</i>
Heat capacity	Low	High	Moderate
Thermal expansion	Moderate	High	Low
Thermal conductivity	High	Very low	Low

**Fig. 4** Electrical resistivity vs Thermal conductivity. Produced using, CES EduPack 2018, 2018. Cambridge: Granta.

Though difficult to include all concepts in one application, at least one or two concepts should be verified when issues of sustainability are considered. Surely, integrating renewable energy sources and energy efficiency concepts are amongst the important concepts of sustainability.

Applying sustainable energy concepts include a wide spectrum of concerns. First, energy is a major component in the process of exploiting resources and transformation of raw materials and ores into useful metallic forms. This concern is becoming more significant with the status of shortages in resources and the need to exploit less convenient ore sites. The increased formation of greenhouse gases with the relevant material processing activities is a major concern. In this context, it should be noted that the more the amount of material needed for an application, the higher will the penalty be on the energy consumption side. Second, sustainable energy concepts include harvesting energy from sustainable and green resources.

The term “embodied energy” refers to the energy consumed in processing and manufacturing of a final engineering part. **Fig. 5** (Ashby, 2012) shows the breakdown of the total life-energy demands of engineering products, from which it is suggested that materials have significant impact. In applications where high strength is a requirement, though the family of composite materials can meet the strength criterion, but their embodied energy is higher than metals and they are not recyclable. The research team from Cambridge University (Ashby, 2012) has presented tables for the embodied energy of conventional key materials being transformed to useful form. For example, the embodied energy of concrete is 1.9 MJ/kg, the embodied energy of plastic is 90 MJ/kg and the embodied energy of steel and aluminum are 20 and 160 MJ/Kg, respectively. However, the situation is not similar for harvesting-green-energy applications, as the strength is not the major requirement. Energy harvesting materials are selected owing to specific physical properties (electrical, optical or thermal). The embodied energy of mono-crystalline silicon solar cells is identified (Holst) to be 1656 MJ/Kg in addition to 432 MJ/m² for wafer processing, 684 MJ/ m² for assembly and 720–1800 MJ/m² for installation. Emerging technologies such as perovskites and organic solar cells often have much lower embodied energies than their silicon counterparts.

The development of materials in modern world for energy applications have opened the door for the inclusion of many types of materials, some of which are known to be toxic and environmentally unfriendly. Moreover, the processing stages of some of these metals or elements from their raw state may include the use of toxic chemicals or the production of environmentally unfriendly by-products. The CES EduPack Sustainability database presents materials data-table containing data for the embodied energies and carbon footprints of materials and processes (Ashby, 2012).

Compared to metals and ceramics, polymers are known to possess low thermal conductivity (0.17–0.23 Wm-1K-1) and relatively high specific heat capacity (polyethylene 1800 Jkg-1 K-1). Those properties, combined with lightweight and low cost, have opened the doors for polymers to be used as low-cost alternative materials for thermal energy conversion and storage

Fig. 5 Breakdown of energy associated to each life-phase. Reproduced from Ashby, M., 2012. The CES EduPack Eco Audit Tool – A White Paper. Version 2.1 © Granta Design Ltd.

applications (El-Mahallawi *et al.*, 2018). The major drawback of the low thermal conductivity of polymers has been resolved in the last decade owing to nanoparticles, nanoplatelets, nanodots and nanofibers.

Polymers in Thermoelectric Applications

Overview of Polymers

The unique material properties of polymers and the versatility of their processing methods are attributed to their molecular structure, which is composed of large molecules (macromolecules) arranged in chains. Polymers have gained their industrial significance from their ease of fabrication, relatively low density, and their ability to be shaped and molded at relatively low temperatures compared to traditional metallic materials. However, the properties of a finished product depend not only on the choice of material and additives but also on the process used to manufacture the part. The relation that exists between the material and product performance is referred to as the 6 P's: Polymer Process, Product, Performance, Post-consumer Life, and Profit (Tim and Osswald, 2010).

Polymers can be classified in many different ways. The most obvious classification is based on the origin of the polymer, i.e., natural vs. synthetic. Other classifications are based on the polymer structure, polymerization mechanism, preparative techniques, or thermal behaviour.

Polymers may be either naturally occurring or purely synthetic. Starch, cellulose, and natural rubber are examples of naturally occurring polymers of enzymes or proteins or plant origins.

Alternatively, polymers are well known among polymers community by their classification according the polymerization mechanism. There are two major methods of polymerization used to convert small molecules (monomers) into polymers. These methods were referred to as addition and condensation polymerization. Addition polymerization is now called chain, chain-growth, or chain reaction polymerization. Condensation is now referred to as step-growth or step-reaction polymerization. The major distinction between these two methods is a result of the differences in the kinetics of the polymerization reaction (Harris, 1981).

Condensation polymers are formed from a series of reactions, often of condensation type, in which any two species (monomers, dimers, trimers, etc.) can react at any time leading to a larger molecule. In condensation polymerization, the stepwise reaction occurs between the chemically reactive groups or functional groups on the reacting molecules. In the process, a small molecule, usually water or ammonia, is eliminated. Addition polymers are produced by reactions in which monomers are added one after another to a rapidly growing chain. The growing polymer in addition polymerization proceeds via a chain mechanism. Like all chain reactions, three fundamental steps are involved: initiation, propagation, and termination. Monomers generally employed in addition polymerization are unsaturated (usually with carbon-carbon double bonds) (Ebewele, 2000).

On the other side, the engineering community distinguishes two classes of polymers, which are thermoplastics and thermosets (Allwood, 2012). Thermoplastics can be melted and reformed several times, while thermosets cure irreversibly upon being heated or treated and cannot be recycled. The basic structural difference between thermoplastics and thermosets is that thermoplastic polymers are composed mainly of linear and branched molecules, whereas thermosets are made up of cross-linked systems. Linear and branched polymers consist of molecules that are not chemically tied together, thus it is possible for individual chains to slide past one another. For cross-linked systems, however, chains are linked chemically; consequently, chains will not flow freely even under the application of heat and pressure. The main thermoplastics and their applications are presented extensively in literature (Allwood, 2012).

Fig. 6 Schematic of direct thermal/electrical energy conversion. Reproduced from Di, C.-A., Xu, W., Zhu, Z., 2016. Organic thermoelectrics for green energy. *National Science Review* 3 (3), 269–271. Available at: <https://doi.org/10.1093/nsr/nww040>.

Recycling and post-consumer life is a major topic within the scope of this article. In this context, the current state of art has reached a satisfactory level for polymer recycling (Allwood, 2012). Reprocessing of plastics has an effect on both flow and mechanical properties of the material, as the molecular weight is reduced each time the material is heated and sheared during the pelletizing and manufacturing process. The reduction in molecular weight is reflected by increases in the melt flow index (MFI), a common technique used to detect degradation (Tim and Osswald, 2010).

Thermoelectrics

Around 90 % of the energy used all over the world is produced by thermal processes which consequently deliver 40% as useful energy and the rest is considered as waste heat (Di *et al.*, 2016), hence waste heat recovery became of interest over the past decades. Waste heat is the generated heat as a by-product of industrial processes, vehicle exhausting systems, housing glass windows and even from human's body skin (Viklund and Johansson, 2014).

Different technologies have been developed over the past decades aiming to harvest as much as possible of the waste heat considering it as a primary source of energy. Thermoelectric generation, solar thermal collectors, phase change materials, thermoacoustic materials, organic rankine cycles are the most trending technologies for waste heat recovery (Oluleye *et al.*, 2016). Thermoelectric generation shows large findings in the field of waste heat recovery and conversion as it enables the direct thermal/electrical energy conversion with no moving parts and robustness device (Fig. 6).

A thermoelectric material is a solid state device that directly converts thermal energy to electrical energy. Its energy conversion efficiency is determined in terms of figure of merit (ZT) which is defined by the relation $ZT = \frac{S^2 \sigma}{\kappa} T$, where S , σ , T and κ are the Seebeck coefficient, electrical conductivity, absolute temperature and thermal conductivity, respectively.

Thermoelectric Materials

Conventional thermoelectric materials have been extensively studied along the past decades to show a deep understanding of their electrical, thermal, thermoelectric behaviour especially for the tellurides and selenides. Tellurium based materials such as Bi_2Te_3 , PbTe and Sb_2Te_3 are characterized to show high ZT (larger than unity) that's why they represent more than 37% of the thermoelectric technologies nowadays as shown in Fig. 7 (Chen *et al.*, 2015; Chhatrasal Gayner and Kar, 2016). Unfortunately, these materials have limited applications in real products as their main building elements are toxic, rare earth and expensive in addition to their processing difficulties and high thermal conductivity (Chen *et al.*, 2015).

On the other hand, though organic based materials have limited contribution to the thermoelectric market, they show an emerging trend in thermoelectric applications (4% of the total thermoelectric technologies) during the last few years with an increasing number of published items and citations as shown in Fig. 8 (Di *et al.*, 2016; Chhatrasal Gayner and Kar, 2016). That's owed to their remarkable advantages of low thermal conductivity, ease of manufacturing and processing, low cost, lightweight, versatility, recyclability, in addition to that, they are considered sustainable and eco-friendly materials (Yao *et al.*, 2010). Organic based thermoelectric materials, that have limited working temperature up to 300°C, target around 89% of the total wasted heat as reported in 2008 based on industrial case study (Fig. 9; Haddad *et al.*, 2014).

Over the past two decades, a large number of polymer based materials and/or composites are reported to be successfully developed for thermoelectric applications. Seeking higher thermal to electrical energy conversion efficiency, large efforts are conducted into fabrication and improvement of novel polymers especially the class of conducting polymers. These developments are performed along variant structure doping, morphological tuning and/or nano-structuring that directly affect the materials' thermoelectric behaviour by manipulating the charge carrier concentration and mobility (Di *et al.*, 2016). Developing

thermoelectric nanocomposites is the second approach to be adopted. This occurs by incorporating inorganic nano-particles with large thermopower into these enhanced semiconducting polymers to result in superior thermoelectric properties (Di *et al.*, 2016). Table 3 shows the most important organic polymers used in this context.

It is shown from Table 3 that the most common polymers in thermoelectric applications include both conducting and insulating polymers. Polyvinyl acetate and polystyrene are commercial polymers that are used only for hosting highly designed

thermoelectric nanoparticles with some contribution to the composite thermoelectric behaviour while the rest are the inherent conducting polymers that are either used stand-alone or incorporated in composites for the purpose of higher thermal/electrical conversion efficiency (Anon, 2015). Despite their inherent low electrical conductivity, all insulating polymers are characterized by low thermal conductivity that offers a great potential for the field of thermoelectrics. Incorporating highly electrical conductivity nano-filler materials; carbon nanotubes (CNTs) or graphene to these polymers can effectively transform the insulating polymer into semiconducting and conducting composites with desirable thermoelectric properties as shown in Fig. 10 (Moriarty *et al.*, 2012; Yu *et al.*, 2011; Badr *et al.*, 2017; Suemori *et al.*, 2013, 2015). Fig. 10 reports the state of art, showing power factor values of

Erden, F., Li, H., Wang, X., Wang, F., He, C., 2018. High-performance thermoelectric materials based on ternary TiO₂/CNT/PANI composites. Physical Chemistry Chemical Physics 20, 9411–9418.

these composites to range from 0.001 to 100 $\mu\text{W}/\text{mK}^2$ or higher according to the different sorts of the used CNTs (single, double and multi walled) and the used stabilizers as reported by Yu *et al.* (2011).

Poly (3, 4-ethylenedioxythiophene), polystyrene sulfonate (PEDOT), PSS and polyaniline are the most common polymers in electronics and optoelectronics applications. Kim *et al.* (2013) reported that the most efficient polymer in thermoelectric applications (EG doped PEDOT: PSS) show a power factor that exceeds 450 $\mu\text{W}/\text{mK}^2$ with specific doping concentration as shown in Fig. 11. The previously reported power factor values of CNTs based composites are also achieved by polymers with conjugated nature that possess semiconducting/conducting characteristics. Badr *et al.* (2017) recently reported the chlorine doping effect on thermoelectric characteristics of pristine PANI as shown in Fig. 11.

In 2012, Lu *et al.* (2012) prepared a hybrid composite of graphene nano sheets (GNs) incorporated into HCl protonated polyaniline by in situ polymerization for thermoelectric use. This composite showed a dramatic increase of the power factor from the pristine materials to that with 30% GNs to reach 2.6 $\mu\text{W}/\text{mK}^2$. In the same year, Yong Du *et al.* (2012) adopted another method of preparation to result in simultaneous increase in both Seebeck coefficient and electrical conductivity by wisely controlling the charge carriers' mobility without affecting their concentration. This occurred by incorporating graphene nano sheets (GNs) in polyaniline (PANI) matrix to reach a higher power factor of 5.6 $\mu\text{W}/\text{mK}^2$ at GNs:PANI ratio of 1:1 at room temperature.

For further improvement of PANI based materials, the ternary composite approach is adopted to reach dual electrical conductivity and thermopower enhancement. Wang *et al.* (2013) achieved the greatest power factor of 146 $\mu\text{W}/\text{mK}^2$ by hosting tellurium nanowires into camphor sulfonic acid (CSA) secondary doped PANI. This large PF is attributed to the energy filtering effect between PANI and Tellurium. Further additions of SWNTs/Te and TiO_2 nanoparticles resulted into 101 and 114.5 $\mu\text{W}/\text{mK}^2$ as reported by Wang *et al.* (2016) and Erden *et al.* (2018) (Fig. 12).

Conclusion

The previous discussion reveals that organic based polymeric materials are promising candidates for future sustainable energy harvesting applications and continuous scientific and technical development will result tuning and development of their properties to meet functional and sustainability challenges.

Background and Challenges

Technology has gone far beyond the thought of an ordinary person and it looks almost casual to handle many of the problems which were too complex to understand just few decades back. Many of such issues will be resolved satisfactorily in years to come relevant to interacting surfaces of different component systems. However, many of the problems remain unresolved mysteries like dolphins avoiding turbulence and maintaining fully laminar flow to move faster than the theory predicts. Even, it is difficult to explain logically the reduction of drag force in pipelines on application of certain polymers and additives. Additives are also used in many more applications such as firefighting, torpedo designing etc. There are many applications for which as tribologists, we need to provide a proper design of component and material which can avoid skidding of automobiles in wet zones, minimise slippage of drive wheels while accelerating, etc. There is virtually endless list of applications posing challenges to tribologists (Moore, 1975).

Further, relentless pressure to develop automobiles, aircrafts etc. with ever increasing fuel efficiency, compact design of engines and stringent environment norms has been another challenge. Looking at it from tribologist point of view, it becomes imperative to design parts as well as materials with capability to bear high specific loads, speeds and temperatures for the major engine components. However, it may not be possible to discuss many aspects in one chapter so, I will be restricting myself only to sustainable materials. In last few decades, advanced composite materials have presented significant benefits and their sustainability has made them accepted engineering materials in many applications. The polymer, metal, or ceramic based composites with different kind of reinforcements, and exceptional tailoring capabilities, can be made suitable for wide range of applications.

Composites as Sustainable Materials

The capability of composites can be clearly understood from few examples of AMCs showing much superior mechanical and tribological properties. These examples clearly show that composites with different reinforcements have superior strength parameters while comparing with corresponding metal/alloy systems. It has been observed that mechanical properties such as ultimate tensile strength, yield strength and hardness improve continuously with increasing amount of reinforcement unless and until clustering of reinforcement takes place due to some reason (Figs. 1–3). It is also interesting to observe many times that ductility also improves with reinforcement (Fig. 4), whereas, in alloy systems with improvement in hardness, ductility is compromised. It is well said that properties of composites can be tailored as per need (Figs. 5 and 6) and these can be designed to meet the requirement i.e., composites can be designed with low coefficient of friction and high wear resistance and also with high coefficient of friction and high wear resistance (Gautam and Mohan, 2016; Kumar *et al.*, 2015; Gautam and Mohan, 2015; Srivastava and Mohan, 2011; Sarkar *et al.*, 2014; Mohan *et al.*, 2002; Pathak *et al.*, 2006; Deppisch *et al.*, 1997; Miranda *et al.*, 2016; Karantzalis *et al.*, 1997; Tee *et al.*, 1999; Kalaiselvan *et al.*, 2011; Gautam *et al.*, 2016a,b; Kumar *et al.*, 2016; Gautam *et al.*, 2016a,b; Mohan *et al.*, 2016a; Agrawal *et al.*, 2014; Mohan *et al.*, 2016b).

Composite Materials

There exist natural composite materials such as timber, bone, tooth etc., but among man made composites the glass reinforced plastic (GRP) was the first composite to be used as an industrial material. However, its potential for aircraft applications could be established only in 1940s, when first time reinforced composite airframe structures were showcased. Tests showed that, it was nearly 50 percent stronger than metallic or wooden structures which were earlier used. Since then such composites have gone long way, and are used in numerous applications related to aircrafts, spacecrafts, sports and recreation goods, marine, automobiles, etc. Infrastructural applications are opening new avenues for composites as commodity material. Metal-matrix are much newer but have found some specialty applications of space shuttle, Hubble telescope etc. and now aluminium matrix composites being very cost effective, are widely in use as automotive material in brakes, drive shafts, and cylinder liners etc. They are also used in electronic packaging and thermal-management applications. Another class with ceramic matrix find applications in cutting tool inserts, wear-resistant parts, aerospace and defense, engines, etc. These have high potential for high performance applications, but due to high cost their applications are limited. However, their high temperature stability, corrosion resistance, and toughness make

them attractive for a wide range of applications. It may not be feasible to discuss all applications due to limitation of a chapter, however, it will be tried to cover few important ones (Hunt, 2011).

Industry-Based Applications

Automotive

Way back in 1940s, Henry Ford introduced an environment friendly car, having body panels made of soybean-resin matrix reinforcement with cellulose-fibers. This car had capability of withstanding high impact loads, with 900 kg less curb weight. Just after few years flying car was presented by Convair. It's body and chassis were of glass-epoxy structural composite. Thereafter, in 1950s, Chevrolet Corvette used body panels of fiberglass reinforced composites. Since then composites are being used in various parts of different automotive vehicles. Today, through structural polymer matrix composites vehicles can be designed to achieve certain goals. The energy crises leading to corporate fuel economy regulations and high rate of taxes on fuels made it imperative to improve efficiency of the automotive engines through more aerodynamic design and weight reduction. Studies have shown that 30% mass reduction in the automobile can reduce fuel consumption by 30%. The potential regions for mass reduction are chassis area which includes the suspension, driveline, braking, and steering components, body and underbody structural systems. The high strength-to-mass ratio of composites makes them suitable to achieve mass reduction. Comparatively higher cost of composites is the main reason that these materials are not dominating automotive industry. Hence, design and property optimization will allow structural composites to be successful in automobiles, pick-up vans, SUVs, etc. in a cost-effective manner (Gianaris, 2001; Musselman, 1997).

Composite materials are engineered and optimized to be fit for structural applications. These materials have high-strength to weight ratio, intermediate to high apparent modulus, and high aspect ratio of fiber with a coherent matrix. They are also

engineered to withstand static and dynamic structural requirements and environmental issues. Further, in case of automobiles appearance, noise level, vibrations of body, process drivers, cost, and safety standards are also very important and must be considered during designing.

Stiffness, strength to weight ratio and weight reduction are treated as design drivers for PMCs in automobiles. Mass reduction in a vehicle system improves fuel economy. The rotating unsprung mass at the hub, wheel, and brake system is very important. Body and the chassis are also mass sensitive regions for vehicle dynamics and performance. The reductions made in unsprung mass improves the performance of vehicle to a much larger level as compared to reduced mass in sprung mass. Hence, mass reduction made in the chassis region, especially the braking/suspension systems improves vehicle dynamics more effectively than reduction in body mass. Additionally, overall mass distribution is very important for dynamics. Any kind of unbalanced reduction is likely to affect dynamics and performance very badly, hence, vehicle dynamics is very crucial. PMCs have inherent advantage of increasing natural frequencies of noise, vibration, and harshness (NVH) in a vehicle while driving. The high stiffness to mass ratios and good damping properties of PMCs increase these frequencies to indistinguishable levels for driver and passenger, hence, these also eliminate the need of additional bushings, other damping materials, and spot welds that are added solely to increase structural stiffness and reduce noise transmission. Therefore, total vehicle mass and cost is further reduced (Gianaris, 2001).

The advantages of structural composites can only be appreciated if we give adequate attention to design principles, process limitations and materials. Engineers need to understand that simply substituting the materials is not enough to have a successful product. Polymer-matrix composites have great potentials for automotive, but the most common mistake made is “direct substitution of materials”. Suppose, a component was originally designed for steel or cast iron, and now it is manufactured with PMCs without any design change, then it will lead to underutilization of PMC capabilities. The specific need of an application must be considered while selecting the material and process, instead of just using a specific material for change. Another critical design driver is related to safety of the vehicle during a crash. The automobile must meet vehicle dynamic and performance expectations that differentiate it from its competition. The reliability and service costs are also quite important (Gianaris, 2001).

Unlike aerospace, applications of structural composites have been limited only to secondary structures in the automotive sector. In aerospace primary and secondary structure are well connected and structural composites have been used extensively for both structures. Role of computer aided engineering (CAE) is very important in automotive design with PMCs. CAE models have been widely used for conventional materials but for PMCs resources are required to develop CAE models. It is also important to

though the need to increase the use of composites to meet fuel economy and safety goals for these vehicles production volume is required. To achieve production volume and to take full advantage of composite material cost, tooling, design optimization, and ownership costs needs to be addressed. Optimized design tools and practices and cost of materials is likely to counterbalance overall cost (Gianaris, 2001).

Solectria Sunrise electric vehicle has been manufactured by stitched woven and braided composite fibers. The entire structure for the body and chassis consists of six separate parts. These were assembled at a cost comparable to conventional structures. Composites have also been used in fuel storage chambers for natural gas storage. These are lighter and more durable

Carrigan *et al.* (2000) and Koppert and Beukers (2000). Development of hydrogen fuel-based powertrains will provide another opportunity for hydrogen storage. High volume production of superior quality low modulus carbon will provide low cost composites which could be used in high stiffness applications like driveshafts (Gianaris, 2001).

Natural fibers like leaf and flax seeds are ecologically friendly and are suitable alternatives for interiors of automobiles. These fibers are lighter with renewability and recyclability properties. Further, low cost, and good thermal and acoustic properties make them more attractive. However, these have certain disadvantages like low strength, limited temperatures of processing, quality variations, absorption of moisture, poor fire resistance, and variable prices. Advancements in these fibers will make them attractive in automotive applications (Brouwer, 2000; Gianaris, 2001).

Metal-Matrix Composites (MMCs) have been in commercial use in number of the automotive applications for several decades because of their low density, high specific stiffness, better high cycle fatigue (HCF) resistance and superior wear resistance (Gianaris, 2001). Though the raw material cost of steel and cast iron is lesser than discontinuously reinforced aluminium (DRA) but it weighs less by 45% which nullifies the cost part. However, wider applications require improvement in performance coupled with innovations in process to bring down the overall cost drastically. But with all these limitations, MMCs have taken over a large share in several engine applications such as pistons, cylinder liners, cylinder blocks, intake and exhaust valves, pushrods, connecting rods, driveshafts, brake system, gears, brake calipers, valves, pump housings, suspension components, supercharger compressors, pulleys, turbocharger, and brackets of certain automobiles. In addition, MMCs are also the candidates for suspension pushrods and rockers, clutch parts, and other gearbox and engine parts (Hunt, 2011; Allison and Cole, 1993; Rittner, 2000; Kevorkian, 1999; Donomoto *et al.*, 1983; Harrigan, 1994; Hamajima *et al.*, 1990; Saito, 1995; Hurley, 1995; Nussbaum, 1997). These applications are already have detailed discussion in another chapter by my colleague so these don't find scope here.

Space

Low coefficient of thermal expansion (CTE), high stiffness, and lifetime dimensional stability are typical requirements of space structures. Hence, these require light weight and high-performance composites. From the beginning of space program solid-fuel rocket motor cases of composites have been used. Continuous developments are being made for launch vehicles, aircraft, spacecraft structures, and missiles. Fiber reinforced laminated composites are very much different in strength, failure mode, elastic response, and damage tolerance properties from metals and alloys. PMCs are also different from metals and alloys in respect to space environment, sensitivity to temperature, and moisture. These things cannot be ignored while choosing designing, manufacturing and test techniques for composites. There have been continuous advancements in manufacturing methods, design & analysis techniques, and fiber quality in last few decades. This has increased composites use in structural and other applications of spacecraft (Lubin, 1982; Policelli and Vicario, 1987; Griffin, 2004; Larson and Wertz, 1992; Rittenhouse and Singletary, 1968; Sarafin, 1995; Schmidt *et al.*, 1999; Strong, 1989; Silverman, 1999; Rule, 1990; Dodson and Rule, 1989; Vicario, 2000; Rawal and Goodman, 2000). The non-structural applications have an extensive list and to name few are optical benches, antenna reflectors, antenna masts, equipment-panel structure, truss structure, electronic enclosures, radiators, engine shields, and solar array support structures. In missiles applications and space launch vehicles composites are used in inter stage structures, payload support structures, rocket motor cases, payload fairings, nozzles, and igniters etc. (Rawal, 2001).

Composites properties such as low density, reduced part count and structural complexity, improved specific strength and stiffness, better dimensional stability, high thermal conductivity, and potentially lower cost than conventional materials make them design drivers for space applications. In space applications, major challenges faced by design engineers are due to allowables limits of properties, manufacturing and testing expenditure, and uncertainty when going for composites. One has to depend on recurring data in the absence of available data for different characteristics of composites. Environment is another major issue because spacecraft are subjected to various environments during various stages starting from fabrication to service life. Designing of structures is mostly governed by earth and space environment. Spacecraft environments include acoustic, transient/steady state, thermal, handling, pyro-shock, vibration, transport, and pressure. Further, structural design is also likely to be affected by other factors like space environment, humidity, ambient temperature, salt-fog etc. The space environment has atomic oxygen (AO), very low-density atmospheric density, ionizing radiation, plasma, charged and neutral particles, micrometeoroids, and anthropogenic debris. Significant change is observed in pressure conditions with altitude in space and it may be about 1.3×10^{-13} Pa for geosynchronous spacecraft, compared to atmospheric pressure of 101.3 kPa at sea level. Exposure to space vacuum, including temperatures variations, PMCs may outgas i.e., release gases. This outgassing causes deterioration of mechanical properties. It is also likely that these gases may condense on critical regions of sensors, lenses, and mirrors, which may influence optical performance (Sarafin, 1995; Vicario, 2000; Rawal and Goodman, 2000; James *et al.*, 1994; Belk *et al.*, 1997; Anderson and Smith, 1994; Dooling and Kinckenor, 1999; Adams *et al.*, 1986; Rawal, 2001).

Composites do offer significant performance improvements in the form of mass reduction, which amounts to \$20,000 for every kilogram of weight saving resulting in reduced launch cost. But choosing constituent materials requires to understand the system in depth. Material choice for spacecraft surfaces is crucial because prevailing temperature and pressure conditions make them prone to atomic oxygen attack. Atomic oxygen has very high percentage in lower earth orbit region (James *et al.*, 1994; Belk *et al.*, 1997; Anderson and Smith, 1994; Dooling and Kinckenor, 1999; Silverman, 1996). The spacecraft material not only faces atomic oxygen erosion, but it also, bears with adverse conditions of solar ultraviolet and high-energy radiation, micrometeoroid and man-made debris impacts, vacuum, cycling of temperature in orbit, and volatilizing condensed organics particles from the surface of spacecraft. The combined effect can cause severe damage to surface's optical, thermal and, mechanical properties. Careful selection and designing of materials can ensure satisfactory performance of the system over a period of time (Rawal, 2001).

Carrying payload is the defined mission of spacecraft and the bus holds components of different subsystems. The bus is the main load path between launch vehicle and components of the spacecraft. The instrumentation part is stationed in bus. Some spacecrafts are using C-C composite nozzle/exit cone parts in the propulsion system. Bus is the main body and it attaches all other parts. Composites provide minimum weight for a particular application and these have to be tailored for high strength/modulus to weight ratio. Composites with carbon/graphite fibers produced from pitch contain highest stiffness and elastic modulus of about 900 GPa. Highly thermally conductive stiff fibers fail at relatively low compressive strength and low strain to failure and are used in applications related to thermal management both structural and non-structural (Rawal, 2001).

Sandwich and isogrid constructions are used in platform structures. Even with low density, both the constructions have high strength to buckling and high stiffness. A composite laminate has adhesively bonded light honeycomb core of aluminium sandwiched between two thin face sheets of composite. Core bears the out-of-plane flexure shear loads while bending moments, axial loads, and in-plane shear loads which act on the panel are dealt by the face-sheets. Bus modules using panel structure have been used in several spacecraft. Taking care of load path, composite bus structures can be designed using simple cylinders, moulded tubes, etc. Most of the bus structure panels are made out of graphite/cyanate or graphite/epoxy composite, but C-C composite has been used in high-temperature structural panels. C-C composite panel, with aluminium core exhibits higher thermal conductivity as well as stiffness while comparing with baseline aluminium panel. This C-C panel has been successfully used as a structural radiator on an operational spacecraft (Vaughn *et al.*, 1998). Aramid and graphite/cyanate esters are used to develop reflectors. These composites materials provide quite high stiffness to weight ratio while coefficient of thermal expansion approaches almost zero. But the laminates and sandwiches of these materials have surprisingly high CTE and coefficient of moisture expansion (CME) through the thickness. It is important to determine CTE and CME to predict as well as to control surface accuracy while fabricating these composites and also when these are in use. PMCs are widely used in many other space applications such as solar array support structures, reflector, avionics boxes/enclosures, attachment fittings, heat sinks for circuit cards, heat sinks for components generating too much heat, radiator fins, and antenna including waveguides (Rawal, 2001).

Though most of the structure related applications are dealt by PMCs, whether, it is structural or non-structural but certain untouched regions have been successfully covered by MMCs and carbon-carbon composites like space shuttle. In space shuttles unidirectional B-Al tubular struts are used as rib truss members and frame in mid fuselage section and also as link of landing gear for space shuttle. These B-Al save about 44% weight from existing ones. Hubble space telescope high-gain antenna boom requires low CTE and high stiffness where diffusion bonded AMC reinforced with graphite fiber has been used. Carbon-carbon composites are used in structural as well as non-structural applications such as radiator, engine shield, thermal doublers, thermal planes, etc. (Anonymous, 1983; Krumweide and Chamberlain, 1988; Rawal, 2001).

Composites are used in various components of space launch vehicle and missile, such as aerodynamic fairings, nozzles, rocket motor cases, launch canisters and control surfaces. Since the early days of lunar missions, fuels and pressurized gases have been stored in the tanks of filament wound composites. Composites have been used in solid rocket motors of nearly all expendable launch vehicles. In the solid-propellant-type motor, fuel burns inside the case and generates moderately high pressures, which is controlled by the large case wall. Low density composites with high tensile strength offer an excellent materials solution. Filament-wound solid rocket motor casings have been extensively used in almost all missile systems, including strategic, ballistic and defensive missile systems that forms the primary system in which Kevlar-49 aramid-fiber/epoxy and standard modulus carbon fiber/epoxy composites are used in different sections. The major composite components of the missile include 1st to 3rd stage rocket motors, equipment section, igniters, etc. (Rawal, 2001).

Aerospace

MMCs are widely used in components related to structural, propulsion, thermal management systems and facing wear problems of commercial as well as military aircrafts. The main motivating factor for MMCs in aeronautics application is their excellent combination of stiffness and specific strength. Due to anisotropic nature, properties of MMCs are limited and generally inferior to organic matrix composites. But discontinuously reinforced aluminium (DRA) with isotropic nature has much superior specific stiffness while comparing with conventional metals and alloys used in such applications. Highest values of specific stiffness are achieved by large volume of particulates but to have good combination of toughness, ductility, and fatigue one needs to limit reinforcement within 25%. These DRAs are isotropic in nature and have nearly 1.5 times higher specific stiffnesses to respective alloys and comparable to most widely used 7075-T6 aluminium alloy as well as Ti-6Al-4V titanium alloy. Discontinuously reinforced titanium (DRTi) has very good structural properties among MMCs. Though, these are new but they find applications in

intake and exhaust valves of automobiles. Efforts have been made to fabricate fiber reinforced metal-matrix composites suitable for aircraft components but with a little success. Many matrices have been used but focus remains on α -, β -, $\alpha + \beta$ titanium alloys and aluminides. Alumina fibers and SiC monofilaments have been common choice but number of problems faced create barrier to their use. Different means have been used to develop these composites. Significant resources have been applied to develop these materials for compressor components of gas turbine engines. In one case, such efforts are still underway, and it is not certain whether a successful insertion will result. Titanium reinforced with fiber has been used for actuator piston rod. Manufacturing of parts with simple shape is easier and due to axial loading material properties are fully utilized. Discontinuously reinforced iron is used in industrial rollers and extrusion dies for wear resistance. Most significant progress has been made in DRAs because of flexible material system where matrix can be cast or wrought alloys while reinforcements can be such as SiC, Al_2O_3 , B_4C . Hence, these are used in wide range specifically in cylinder liners, snow tire studs etc. and in broader prospective in application related to space, automotive, thermal management etc. (Miracle, 2001).

Aero-structural

During flight ventral fins are subjected to unexpected turbulence situations. The turbulent air originates in the front engine intake and propagates along fuselage. Ventral fins observe rolling effect causing bending movement. In this process bolt holes are elongated and eventually failure takes place. Though there is no life risk for pilot or damage to aircraft, but it leads to heavy cost as well as repair time. High strength and stiffness of the material is very important (Miracle, 2001). 2024-T4 aluminium alloy has been a choice for ventral fin structure. The inner structure comprises of a central root rib projecting normal to skin of fuselage while front and rear spar are in parallel direction to the fuselage skin. Honeycomb core and sheet complete the assembly. Design trade studies have been used to find the solution to ventral fin failure. These studies show that critical designing requires strength to high cycle fatigue (HCF) and excellent stiffness. Initial solution suggested to use graphite/epoxy skin above spar to increase thickness of the original 2024-T4 aluminium alloy, and a discontinuously reinforce sheet above Al-alloy spar. However, it failed due to cost issues. 6092 age hardenable aluminium alloy was optimized as matrix alloy for 17.5pSiC reinforced DRA. This material showed 40% higher specific stiffness over the baseline design. It removed torsional load on fin and restricted elongation of bolt hole. About 50% reduction in peak tip deflection was also observed. Ventral fins of DRA reduced the downtime as well as inspection and maintenance cost. It results in overall life cycle cost. Further, this composite has also been used to tackle the problem of cracking in fuel access door covers near the vertical tail root. In order to reduce stress at opening door fasteners were re-designed. Changed design was more compatible with improved HCF resistance. This design with changed material also provided improved bearing properties, higher strength and stiffness. Improved designing of doors and fasteners by DRA reduced the peak skin stress by 38%, and average skin stress by 10% and cracking issue was completely resolved (Miracle, 2001).

The helicopter blade sleeve has an important function of supporting centrifugal load of rotor blades to drive shaft. Hence, it requires a set of properties like excellent resistance to fretting fatigue, high specific strength, good fracture toughness and endless fatigue life. Rotating mass is key to performance and durability of Helicopter so reduction in rotating mass is likely to improve life and performance. If the original material is titanium alloy cost also becomes important. It has been replaced by forged DRA (2009/SiC/15p-T4). DRA has a fatigue strength of 270 MPa. The excellent strength, good fracture toughness, comparable specific strength to titanium alloy along with weight reduction of about 14 kg in rotating mass has made the DRA front runner. Lastly, it also reduces the cost of the part (Miracle, 2001).

Aero-propulsion

It is important to get maximum thrust from redirected air to move forward. The fan exit guide vane (FEGV) of high-bypass gas turbine engines has an important role of removing swirl component of bypassing air which may cause hinderance in forward motion. The primary design in commercial engines requires excellent resistance to air erosion due to particles, high specific stiffness, and ballistic response, however, support cost part is also important and cannot be ignored. The graphite/epoxy used for the application did not have adequate ballistic response, had poor performance due to airborne particulates erosion and rain. It increased service cost and even flight safety was at stake. Though, Ti-alloy foil on leading edges provided slight improvement on erosion aspect but no change in ballistic performance could be bought with highly expensive Ti-alloy. Finally, billets of P/M produced 6092/SiC/17.5p DRA were used as replacement. Its proper particle distribution after extrusion improved fracture properties. The DRA design exhibited seven times reduction in erosion and remarkable improvement in resistance to ballistic damage. This composite reduced the unit cost and increased the service life by three times, and also reduced repair and maintenance (Miracle, 2001).

Direction and velocity of exhaust gases is very important in efficiency of gas turbine engines and both of these are controlled by engine nozzle flap position through actuator and linkage devices. The actuator assembly consisting of a hydraulic cylinder and a metallic piston with linkage mechanism, drives the all divergent nozzle flaps. The piston must support large axial loads and also possess high stiffness. Precipitation hardened 13-8 Cr-Ni stainless steel solid rod has been the specified material. The piston rod operating temperature is about 450°C and it requires good fatigue strength, specific strength and stiffness. It has been replaced by MMC containing titanium alloy reinforced with SiC fibers. Titanium matrix composite (TMC) saves about 13.4 kg of weight and this being in aft end counter weights so it can also be removed/minimized which provides further weight saving. F110 engine nozzle has 24 nozzle flaps around the exhaust periphery. Every second nozzle flap requires one actuator via a nozzle link which amounts to total 12 nozzle link actuators of TMC for an engine. Inconel 718 was used for original link from a square tube. The TMC link saves weight by 2 kg per shipset and improves buckling resistance as compared to Inconel 718 component (Miracle, 2001).

6091/SiC/25p DRA has been the first composite to be used in the history of military aircraft application as avionics support racks. The primary requirements for the application is high electrical conductivity, good bearing strength, and isotropic stiffness. The graphite/epoxy replaced original structure was an aluminium alloy for weight saving, but this also lacked isotropic stiffness and bearing properties. Issue was tackled by several modes but other problems arose and success was not achieved. Finally, DRA solved the issue with minimum gage thickness extruded tubes. It provided good bearing strength along with the high intrinsic electrical conductivity and weight saving of 20% as compared to graphite/epoxy and 34% to original aluminium design. Reduced material costs led to reduced component cost (Miracle, 2001).

DRA's are used in naval aircrafts for hydraulic manifolds. These manifolds redistribute hydraulic fluid with high pressure of about 70 MPa to flight controlling surfaces. In addition, manifolds are subjected to impulse loading at an operating temperature of about 100°C. Material used should have near net shape processing capability, good resistance to HCF due to impulse loading and high specific strength. The initial material i.e., 7050 aluminium was not successful due to failing in burst tests so as replacement 2009/SiC/15w DRA with whisker reinforced was successfully used satisfying service requirements, but high cost due to whiskers and machining remained bottleneck. Alternatively, A206/SiC/40p DRA produced through pressure infiltration casting was also used. This can be produced with near net shape capability with 30%–70% vol. fractions SiC. The component produced by DRA provides weight saving, with lower CTE, superior wear resistance, and much better fatigue properties which is unique because in general Al-alloys have poor fatigue response in hydraulic fluid for pressures exceeding 34 MPa. Hence, DRA components are becoming replacement to titanium alloys in such applications due to much lower cost (Miracle, 2001).

Size-based

FRPs have replaced existing materials in many components in aircraft related applications. Composites are strong, fatigue resistant, damage tolerant, and have been shown to be very durable when the design of the component includes proper consideration for the operating environment common to the component. They satisfy designing and certification compulsions with mass reduction. Cost reductions, especially in aircraft life-cycle makes them ahead of other materials. Fibers or filaments are common reinforcements in composites which are used in aircrafts related components. Carbon, glass, aramid are common fibers but carbon is used most widely among these. These are generally used in epoxy base resin matrix (Wilhelm, 2001).

Composite components are used extensively on current commercial aircrafts weighing about 1500 kg, while smaller planes use approximately 680 kg. The vertical fin of the Airbus A310 was produced from carbon-reinforced epoxy as a production commitment and certified. A twin jet Boeing aircraft contains approximately 7450 kg of carbon- and fiberglass-composite material; 71% of this amount is carbon reinforced and it doesn't include the payload interiors. The majority of the carbon/epoxy quantity is an intermediate modulus fiber impregnated with a toughened epoxy base matrix used in floor beams, the horizontal stabilizer, and the vertical fin. On the 737, composites are used for control surfaces, fairings, and nacelle components for about 3% of the total structural weight of the aircraft. Individual composite parts are 20%–30% lighter than their metallic counterparts. Small, general aviation airplanes make extensive use of advanced carbon-, glass-, and aramid-fiber based composites up to 820–1360 kg per aircraft. Honeycomb sandwich structure is most common except for few parts. Structures like fairings, fixed wings, trailing edge panels are mostly sandwiched structures. Face sheets for panels are produced by only carbon or hybrid fibers. Composites are becoming important even in interiors applications. Apart from other requirements, now it is mandatory pass flammability resistance test and smoke and toxic-gas emission guidelines. Additionally, visible portions of interior components must meet stringent aesthetic requirements to satisfy the airlines and their customers. Most of the interior region like luggage bins, walls, ceilings, floors, lavatories, etc. are made of composite. Either, fiber reinforced epoxy or phenolic resin honeycomb sandwich structures are used. Apart from fire resistant properties interior components are required to have impact resistance, stiffness, and surface smoothness (Wilhelm, 2001).

Composites are most widely (about 40%) used in U.S. military related programs. Most military aircrafts use carbon-fiber-reinforcement in epoxy. Carbon fiber reinforced composites constitute about 26% of the structural weight of the U.S. Naval AV-8B aircraft. Components using composites are forward fuselage, wing box, elevators, horizontal stabilizer, rudder & other control surfaces, and over wing fairings. The wing skins is single piece laminate, mechanically fastened composite. AV-8B uses nearly 590 kg of carbon-fiber epoxy and reduces the weight almost by 225 kg. Carbon fiber composites constitute about 10% of F-18 aircraft structural weight and about 50% of surface area. These are used in wing skins, tail boxes, control surfaces, speed brake, doors and leading-edge extensions. At a production rate of four aircraft per month, the B-1B uses 127,000 kg per year of composite structure, i.e., 3040 kg per aircraft that results in weight savings of approximately 1360 kg on each bomber (Wilhelm, 2001).

Marine

FRP composites use started in boat building due to increasing timber cost. Seawater and marine organisms degrade the timber hulls and that ends up with high maintenance and repairing cost (Buermann and Della Rocca, 1960; Spaulding, 1966; Heller, 1967). It led to the use of composites in different marine crafts, and with time it got extended to lightweight structures on warships. Composites have large number of application in leisure craft, yachts, boats, ships, submarines, and offshore structures (Mouritz, 2001; Greene, 1990; Graner, 1982; Smith, 1990; Mouritz *et al.*, 2001).

Naval

The main objective to use FRP composites was to have lightweight, strong, corrosion resistant, and durable naval boats. US Navy used composites in large ships deckhouses, pipes, fuel and water tanks, submarines fairwaters and mast shrouds (Buermann and Della Rocca, 1960; Spaulding, 1966; Heller, 1967). Later, navies of many other countries also started using composites and just in decades time their use increased several folds in marine applications (Henton, 1967; Mäkinen *et al.*, 1998).

The problem of stiffness for low hull girder for small warships was resolved in early 1970s with the construction of the Royal Navy minesweeper HMS Wilton (Dixon *et al.*, 1972; Chalmers *et al.*, 1984). A thin FRP laminate shell stiffened with longitudinal and transverse frames, mostly of sandwiched structure solved the problem and hull girder with high stiffness was achieved. It's frame was single-skin design of composite construction. Other requirements of naval ships like good impact strength and underwater blast damage resistance were also fulfilled (Mouritz *et al.*, 2001). Apart from single skin hull, two other hull forms of composite have also been developed which consist of thick laminate hull and sandwich construction hull (Smith, 1990). FRP patrol boats became popular mainly due to reduced maintenance cost because of excellent corrosion resistance and light weight resulting in high speed and improved fuel economy. Composite reduces 10% weight as compared to aluminium and 35% as compared to steel (Goubalt and Mayes, 1996) but major drawback is nearly 30% higher cost. Composite propellers, propulsors, and propulsion shafts are also being worked out. Composites are expected to offer several benefits over metals in propulsion systems like low cost, reduced weight, lower magnetic signature, improved damping properties, and superior corrosion resistance. It is important to understand switching over from steel to composite in propulsion shafts because it will reduce weight by 25%–80% with same size and life-cycle costs will reduce at least by 25% due to lesser corrosion and fatigue problems. Though, at present the use is very limited but with time it is expected to increase several folds in applications including funnels, bulkheads, decks, watertight doors, machinery foundations, pipes, ventilation ducts, and components for diesel engines, pumps, and heat exchangers on large warships (Mouritz *et al.*, 2001; Goubalt and Mayes, 1996; Horsman, 1994; Kane and Dow, 1994; Macander, 1994; Foxwell, 1999; Womack, 1993; Pegg and Reyes, 1987; Searle and Shot, 1994; Wilhelmi *et al.*, 1986; Gagorik *et al.*, 1991; Phelan, 1995; Bhasin *et al.*, 1998; Suitt and Girona, 1993; Wilhelmi and Schab, 1977).

Offshore

Offshore drilling platforms are using FRP composites for quite some time, though these are used only in niche applications (Williams, 1990). Apart from cost cutting and outstanding corrosion resistance, composites also provide opportunity to reduce topside weight of offshore platforms. The important applications are accommodation modules, helicopter landing pads, and decks, where, weight saving of 30%–50% can be achieved. Currently, FRPs are used in low pressure pipes, diesel storage-, lube-, and utility tanks, walkway gratings, stair steps, handrails, cable ladders, fire protection panels, strengthening of primary steel structures, helicopter landing decks, etc. Composites use is expected to increase with time once economic and technical issues are resolved (Williams, 1990; Barnes, 1996; Mouritz, 2001; McConnell, 1996; Goldsworthy and Wiernicki, 1990; Godfrey and Davis, 1990; Gibson, 1993).

Thermal Management and Electronic Packaging

Advanced composites provide many advantages over traditional materials in thermal management and microelectronic packaging such as thermal conductivity more than double of copper, low CTE with tailorable capability, 80% weight saving, about 65% reduction in size, excellent strength and stiffness, less thermal stresses, increased reliability, simple thermal design, potential elimination of heat pipes, reduced cost and net-shape fabrication capabilities (Zweben, 2001a,b). Combining two or more constituents creates material with unique set of properties for which no example can be better than printed circuit boards (PCBs) for which dielectric properties are very critical. The most common PCB material, E-glass fiber-reinforced epoxy, was first developed over a half century ago. In addition to microelectronic packaging, composites are also suitable in other applications including optoelectronics and microelectromechanical systems (MEMS) (Schmidt and Zweben, 1989; Kelly, 1988).

Packaging parts are produced from several hundreds to thousands per annum. Copper- and aluminium based composites are most common, however, discontinuous thermally conductive carbon-fiber-reinforced polymers are also not far behind. Microelectronic packaging components include carriers, hermetic microwave packages, power semiconductor packages, liquid cooled PCB cold plates, heat sinks, thermal straps, enclosures, and support structures (Sangha *et al.*, 1997; Thaw *et al.*, 1987a,b,c; Zweben, 1988; Schmidt and Zweben, 1988; Zweben, 1992; Miller, 1995; Shih *et al.*, 1994b; Montesano, 1996; DiNardo *et al.*, 1990; Zweben, 1995; Fleming *et al.*, 1995; Chung, 1995; Zweben, 1998a,b,c,d,e; Chung and Zweben, 2000; Zweben, 1999a,b). Spacecraft applications include radiators, radiator panel thermal doublers, and battery sleeves. The composite electronic packaging components are being used in commercial and aerospace such as electric vehicles, motor controllers, cellular telephone ground stations, laptops, and also in microwave and power supply subsystems. Composites are key to integrated multifunctional structural/electronic systems (Kuhn *et al.*, 1999; Zweben, 1999a,b; Rawal and Goodman, 2000; Rawal, 2000; Zweben, 2001a,b).

Sports and Recreation

The advantages of composite construction have been applied to equipment for a wide range of sports and recreation activities. These advantages include strength, ductility, stiffness (modulus), and low density (Easterling, 1993). Laminated wood construction or plywood, was later used in various forms for sport and pleasure boating, as well as in tennis rackets and the delicate

glued flyrods constructed of tapered bamboo sections. More recently, the term composite has been associated with such materials as fiberglass, carbon fibers, silicon carbide platelets and whiskers, and aramid fibers. These materials have greatly broadened composite use in sports and recreational equipments by introducing filamentary materials whose tensile strength to weight and stiffness properties are far superior than those of wood, steel, and other more common materials.

Bats, rackets, and clubs

Nowadays softball teams and college baseball teams are generally using composite bats. These bats are made of a graphite-reinforced polycarbonate. The graphite-reinforced bat is lighter and durable just like aluminium and has sound of wood. The bat is extremely resistant to impact which is very important property of a bat. It has been tested against air cannon which rockets balls at 290 km/h. The graphite-reinforced resin shell is light, strong, and stiff. The weight savings allows greater options in the placement of the urethane filler. Graphite also helps to reduce vibrations as well as shock and tingling feeling in hands given by ball. The centre of gravity of the bat also can be moved down the handle which allows the hitter to generate more bat speed. With a larger sweet spot and greater bat speed, sports person can hit the ball to far more distance (Anonymous, 2001).

Many professionals smash the tennis balls over 160 km/h speed. It is a game of speed as well as control. Hitting and receiving ball at high speeds requires high level of concentration and great degree of control over racket. Rackets made of graphite-fibers composites provide better control of ball without using excessive physical energy. The graphite rackets are much stronger and stiffer while comparing with metal or wood. These rackets also have lesser head torque that provides a solid feeling over a larger area of the racket head to a player. A graphite racket dissipates less energy, allowing the player to hit the ball with greater speed. Weight and balance of the racket can be tailored according to individual player's needs. The endurance life of a graphite racket is also more than that of conventional rackets. Composite rackets can also be made with a combination of unidirectional and braided carbon fibers. Braided carbon fibers restricts twisting of racket. Rackets are made of about 65% carbon, 30% glass, and 5% aramid. Graphite provides stiffness with brittleness; fiberglass provides flexibility with toughness. Rackets are also made out of 84% carbon, 12% aramid, and 4% alumina fibers. It provides the comfort of ceramic and performance of carbon. Carbon provides controlled power with good combination of stiffness and strength. Aramid provides damping property and prevents "tennis elbow" (Anonymous, 2001).

Composite golf shafts, reinforced with graphite fibers, helps golfer to have better control over the game. It is 40% lighter than conventional one, hence, allows weight to be added to the club head, while still have lesser overall club weight. Larger head weight ball is driven farther while lighter side of the club helps the golfer to remain accurate with his shots. These golf shafts are usually produced by either roll wrapping or filament winding. Golf club shafts are made of combination of carbon- and boron-fiber reinforcement. Larger fiber diameter of boron as compared to carbon helps to serve better when used longitudinally (Anonymous, 2001).

Bicycling

Cycling need training, endurance, strategy, and well-designed equipment. Bike racing also need high level of concentration. Energy should not be wasted in unnecessary moves. During pedalling, power should be transmitted all the way, and it is obvious that lighter the bicycle faster it will go. Carbon-fiber-reinforced bicycle frames are lighter than aluminium and stiffer than steel. Hubs and wheels are designed from glass fiber reinforced nylon. Normal drive plates and drive chains have been replaced by PMC. Bicycle frames are composed of G/epoxy composite allowing flexibility in designing with reduced drag. They also provide damping against vibrations. The suspension system is made of graphite and glass which reduces shock. Graphite braided bicycle frames are used to achieve high level of strength and torsion resistance or twisting. In another design with carbon/epoxy frame there is no seat tube. This single-piece frame with integrally moulded tubes uses a passive suspension system that provides smooth and aerodynamic ride. In another single-piece design, true airfoils are used to reduce the drag. It has hybrid reinforcement of carbon and polyethylene (PE). Carbon fibers provide stiffness, and PE is responsible for lightweight strength. PE fibers resist shocks and fatigue. Stress concentration regions are absent due to unavailability of bonded joints. Composite frames are more flexible and easier on bumps, so helpful in long races. It is also important that composite frames provide three to four times better fatigue and crushing strength than steel. Air resistance is the major cause to slow down the speed of cyclist and it amounts to 90% of the total force. C-C composite tubes are used to provide airfoil shape to bicycle frame which helps to reduce the drag. Boron-reinforced aluminium is also used for frame and these are lighter, stiffer and stronger than aluminium. Composite spoke and disc wheels are also used. Carbon- fiber-reinforced polymer composites in combination with titanium, have been used (Anonymous, 2001).

Carbon-fiber reinforced nylon has been used for spin bicycle wheels. The spin wheel three-spoke is a one-piece hollow construction. It is stronger and lighter with half the cost of traditional carbon/ epoxy wheel. Aramid-fiber composites are used in disc wheels. The aramid wheels reduce the wind resistance of a normal bicycle wheel. Aramid-reinforced tires are lighter than 0.1 kg and these feather-light wheels and tires help to reduce rolling friction to a large extent (Anonymous, 2001).

Environment-Based Applications

High Temperature

High temperature polymers are being used in applications such as aerospace, electronics, and other applications demanding elevated temperature, physical and mechanical properties. Major product forms of such polymers include fibers, coatings,

adhesives, foam, film, insulating paper laminating resin solutions, wire enamels and moulding powders. In the beginning, PMCs with fiber reinforcement were used only in high temperature non-structural (non-load bearing) components. However, with in situ polymerization of monomer reactants (PMR) polyimides (Serafini *et al.*, 1972; Serafini *et al.*, 1973; Serafini, 1976) and their commercialization, the fiber-reinforced PMR polyimide based on PMR-15 became increasingly acceptable as high-performance engineering material for structural applications. Other resins that have found use in composites for high-temperature applications include phenolics and bismaleimides (Serafini, 2001).

In a composite, matrix must bind the fiber reinforcement for a material to function as a viable matrix. It should also be transferring load, provide processability and environment stability. Organic polymers generally melt below 200°C. Preparing high-temperature polymers requires incorporation of structural units of high stability in the polymer chain. These structural units absorb thermal energy and contain minimum oxidizable hydrogen atoms. Apart from high temperature capabilities polymers are also resistant to processed into structural components. Composites prepared from these polymers exhibit too much voids, poor translation ability of fibers, poor high-temperature mechanical properties, as well as thermo-oxidative stabilities. Though thermal ability could be improved but processing part remained neglected (Serafini, 2001).

High-temperature condensation-type polyimides commercialized in 1960s and became single competitor for resin-matrix applications. These materials had processing problems but these had very good high-temperature properties, easy availability and low cost. The initial applications these fiber-reinforced polyimides were radomes for advanced aircraft (Poveromo, 1983) and for sound-suppression panels in the engine nacelles of subsonic commercial transports. Both were secondary structural applications. It was observed that high void content of such polyimides could be desirable for the sound-suppression panels (Serafini, 2001). Major breakthrough in high-temperature resins was to develop polyimides that could be cured by an addition reaction (Lubowitz, 1970; Burns *et al.*, 1968). Earlier studies (Serafini *et al.*, 1972; Delvigs *et al.*, 1972) have shown ability and versatile nature of the PMR approach. Fiber-reinforced PMR composites have been fabricated by high pressure as well as low pressure moulding cycles (Vannucci, 1977).

The development of PMR-15 resin increased the number of applications of composite components for high-temperature. Earlier resin systems had serious size and thickness limitations for potential applications; however, development of PMR-15 opened-up large avenues for design engineers for large, complex and thick sections components. PMR-15 became interesting material for military propulsion community, due to the high operating temperatures within the low-pressure system. Its high weight savings led its use in both rotor blades and stator vanes. The blade was the first structural airfoil component which could be developed with PMR-15 and could be reinforced with high tensile strength graphite fiber. The blade was designed and developed for ultrahigh-speed fan stage (Halle *et al.*, 1977; Cavano, 1974). The thickest section of the composite consisted of 77 plies of arranged in different fiber orientations. The torsional stiffness requirements could be met with different orientation of fibers with height. Although some internal defects were observed in the blade while going for LCF and HCF but PMR-15 got established as a processible matrix resin. Another application of PMR-15 composites in rotating components was the fourth-stage compressor blade shells and spacers of supersonic wind tunnel. Almost 11,000 kg fiberglass-PMR-15 were used for the application and total amount was equally divided for 360 blade shells and 600 blade spacers. The success with small airfoil components created interest to use PMR-15 in large static structures. The most aggressive use of composite was to apply it in propulsion system. To achieve the goals for low weight, low noise, clean emissions, and improved efficiency, composites were extensively used in the vane frame, fan blades, integrated nacelle, external flaps, containment, inlet, and inner core cowl. The blades, frame, and nacelle components were produced out of carbon- epoxy tape and fabric; the containment with aramid fabric; and the inner core cowl with graphite-PMR-15 fabric. The high-temperature at core cowl was due to radiant heating at shutdown. The absence of airflow raised the temperature approximately to 315°C. The core cowl was a honeycomb sandwich structure. Polyimide reinforced with fiberglass has been used for core. To control acoustic emissions, the flowpath of the core cowl was perforated with 0.5 mm holes to have 10% porosity level. The use of cowl for 300 h without any degradation established the feasibility of using graphite-PMR-15 composites in large structures (Adamson, 1979; Stotler, 1979; Serafini, 2001).

Material-Based Applications

Carbon–Carbon Composites

Carbon–carbon composites have been utilized for applications requiring ablation and high temperature stability (i.e., rocket nozzles and exit cones) or wear resistance at moderate temperatures (i.e., aircraft brakes). In mid-1980s, these were considered stiff thin walls. This interest has led to the investigation into other properties of carbon that could be exploited in a carbon–carbon composite. One area that has been explored is carbon–carbon for thermal management. Many systems require heat control, either by rejecting or by absorbing “waste heat energy.” This has led to much interest in carbon–carbon for such applications as electronic thermal planes; thermal doublers, radiators, and thermal and shields; and heat exchangers. Carbon has many characteristics that are appealing for many different thermal management applications. It's very low density, a tailorable thermal conductivity, and very low CTE with acceptable mechanical properties has made it important in large number of applications. This implies that a carbon composite can be fabricated with high specific thermal conductivity and low CTE. These properties are very desirable for many different thermal management applications (Kearns, 2001).

Thermal planes for electronics is one among many thermal management applications of C–C composites. Electronic board need to maintain a temperature at which they can properly operate, so the thermal plane should be capable of dissipating heat i.e.,

it should have good thermal conductivity. The thermal plane should also have low CTE so that it doesn't expand much under heat loads. Otherwise wearing of board may attach the chips to electronic board. High stiffness of material is important to restrict transmission of vibrations to electronic board that reduces fatigue load on the joints and also reduces deflections. Electronic boards having less deflection under load can be easily packed together without impact risk. This allows a designer to provide more electronic capability within small volume. C-C is very suitable for such application with low CTE and high thermal conductivity. It reduces electronic packaging temperature by 4–16°C, as compared to conventional aluminium thermal plane. This temperature reduction increases the reliability of packaging. Further, its high stiffness restricts the deflections during vibrational loading. Its low density also suits electronic thermal planes.

Spacecraft thermal doublers have same function as that of thermal planes, but it has different mechanical requirements. The thermal doubler removes the heat from different parts of spacecraft and allows its radiation to space that requires material with high thermal conductivity. A light weight thermal doubler is needed to be attached to components requiring low stiffness to reduce vibration. The weight of spacecraft considerably affects the cost of launching a spacecraft. Hence, designers need a low-density material to meet the performance. C-C composite fulfils all the requirement of a thermal doubler properties. Choosing a low-modulus fiber of high conductivity with appropriate architecture, composite can be prepared with low-modulus. C-C thermal doublers have been used on some spacecraft. Spacecraft thermal shields constitute a different type of thermal management application. Its shields rest of the spacecraft from useless heat of the propulsion system. Hence, it requires high-temperature stability, low density, and high stiffness. It also requires stability at high temperatures to take care of heat which is generated by the propulsion system. It should also be able to respond well to high vibrational loading from the acoustics. C-C composites provide a thermal shield almost with 50% weight reduction over metallic ones. These composites have proven record to maintain temperature stability and stiffness which ensures their successful performance in thermal shields. Spacecraft radiators also need a material with ability to conduct waste heat from a source to space. Its function is to maintain all attachments cool enough to operate properly, hence, high thermal conductivity, good strength & stiffness, and low density are the main requirements of a material. A carbon-carbon composites possesses most of the needed properties (Kearns, 2001).

Different heat exchangers are used on different systems in an aircraft. The operating conditions touch temperature as high as 650°C with low to high fluid pressures. The specific conditions depend on the location and functioning of heat exchanger in the aircraft. The function of the heat-exchanger material is basically to dissipate heat from the hot fluid to the cold. The material requires high thermal conductivity, good corrosion resistance, reasonable strength, stiffness, with low permeability, and moderate temperature capability depending on location and functioning of heat exchanger. Corrosion resistance is needed to take care of the fluids running through heat-exchanger channels. For aircraft flying over the oceans ingests salt spray, therefore, resistant to saltwater corrosion or maintenance costs will be high. For the lower-temperature heat exchangers with air fluids, carbon-carbon may be the ideal material due to its unique properties. Corrosion doesn't bother at temperatures below 370°C. In higher-temperature heat exchangers weight savings and high thermal conductivity of carbon-carbon offers the payoff of a higher-performance. But many issues need to be addressed in having a C-C carbon-carbon heat exchanger. The core consists of parting plates and fins which is a delicate design for composites. The core structure with carbon-carbon must be highly automated for better reproducibility, quality and low cost. Carbon starts oxidizing in the presence of oxygen at high temperature which require oxidation protection schemes for heat exchangers working above 370°C (Wilhelm, 2001; Schmidt *et al.*, 1999; Shih *et al.*, 1994a; Rawal, 2000; Kearns, 2001).

Ceramic-Matrix Composites

Ceramic-matrix composites' (CMCs) applications fall in four major groups (Davis, 1995, 2001; Abraham, 2000):

- Cutting tool
- Wear
- Aerospace and military parts
- Other applications

CMCs involves discontinuous reinforcement of particles, whiskers, chopped fibers, etc. into polycrystalline ceramic, glass, or glass-ceramic matrix. From industrial application viewpoint, alumina (Al_2O_3) is the most important matrix material, though, such composites have also been produced from silicon carbide (SiC), silicon nitride (Si_3N_4), mullite ($3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$), and aluminosilicate matrices while important reinforcements have been SiC, zirconia (ZrO_2), and titanium carbide (TiC) etc. (Davis, 2001).

Cutting tools

Both particulates and whiskers are widely used as reinforcements. Al_2O_3 is used in cutting tool inserts. The development of these composites as tool materials has been based on high temperature ceramics as well as on process developments for applications related to automobile gas turbine and high temperature structural applications. Al_2O_3 -TiC Composites can produce a cutting tool with superior hardness and fracture resistance if these are hot-pressed or hot isostatically pressed consisting of approximately 70%

Al_2O_3 with 30% TiC particulate. These are known as black ceramics due to their dark colour, which is due to the presence of TiC (Davis, 2001).

The hard-refractory particles when dispersed increase the hardness of these composites for the temperature up to 800°C comparing to monolithic oxide ceramics. Further, impediment, deflection, and/or branching of cracks due to dispersed hard particles increase the fracture toughness and bending strength. Combination of higher hardness with high toughness improves the resistance to abrasion and erosion considerably. High thermal conductivity combined with low CTE of composites exhibits improved thermal shock resistance as compared to monolithic oxide ceramics. TiC particles oxidize and lose reinforcing properties as the temperature exceeds 800°C, which weaken the composite. This phenomenon needs to be taken into account while selecting cutting conditions like speed, depth, and feed rate. The HIPed Al_2O_3 -TiC composite tool grades are used for interrupted cutting, finishing etc. of high-temperature superalloys, hardened steels up to 50 HRC, chilled irons with hardness up to 60 HRC and gray and ductile cast irons with high hardness. Al_2O_3 -SiCw is the recent alumina base tool material. In these 20–45 vol% SiC whiskers are added and subsequently it is hot-pressed which provides good toughness. The whiskers have high thermal conductivity and low CTE than Al_2O_3 . It leads to improved thermal-shock resistance. The SiC whiskers improve fracture toughness. High level of energy is required to pull out the whiskers, and this greatly inhibits crack propagation (Wei and Becher, 1985; Tieg and Becher, 1986; Jun and Smith, 1994; Davis, 2001).

The Al_2O_3 -SiCw tool grades composite are used for rough turning of alloys, hardened steels etc. Their main primary application is roughing, finishing, and milling of difficult-to-machine alloys and superalloys parts. They provide much higher cutting speeds and longer tool life. Si_3N_4 -base particle-reinforced and whisker-reinforced composites have also been tested as cutting tool materials (Buljan and Sarin, 1981, 1982; Sarin and Buljan, 1983; Baldoni and Buljan, 1986; Hampshire, 1991). The addition phases such as TiC, TiN, and HfC to a Si_3N_4 matrix improves hardness. Hot-pressed composites, reinforced with 10–30 vol% SiC whiskers exhibit higher fracture toughness than their unreinforced parts. Despite many advantages, Si_3N_4 -base composite tool materials are yet to reach commercial viability (Davis, 2001).

Wear-resistant

Ceramic toughened through zirconia particulate are finding applications in bushings, bearings, precision balls, valve seats, die inserts etc., where both friction and wear resistance are improved. One example is zirconia-toughened alumina, or ZTA, where Al_2O_3 is continuous phase with 70–95 vol%. Zirconia particulate additions from 5% to 30% represent the second phase (Davis, 2001).

The microstructure and mechanical properties can be tailored for particular application. High ZrO_2 content improves strength and fracture toughness, but hardness and elastic modulus are slightly reduced. Strengths of 1050 MPa and fracture toughness of 8.0 MPa are achievable. Wear properties also find improvement in certain applications. Such compositions of ZTA have been used in transportation applications because these can withstand erosion, abrasion, corrosion, and thermal shock. ZTA are also used in cutting tool inserts and abrasive grinding medium. ZTA have also shown important properties related to thermal shock applications (Davis, 2001).

Coarse SiC particles reinforcement Al_2O_3 matrix composite have shown good slurry erosion resistance (Weinstein and Rossing, 1990; Rossing and Rocazella, 1990), hence these are used in slurry pump components, hydro-cyclone and chute liners, and also in materials handling systems. A similar type of composite is also used in armor applications. SiC particle reinforced Al_2O_3 matrix composite has also been optimized for sliding and rolling contact wear application (Urquhart, 1991). It has fine SiC particles with modifications in Al_2O_3 ceramic matrix. Favourable prototype test results have been observed for piston, engine cam, follower, rollers (Davis, 2001). CMC has also been accepted in aluminium can-making equipment and associated tooling. Products made from CMCs include punches, redraw dies, ironing dies, pressure rings, domer tooling, cupper tooling, stripper tooling, necker tooling, trimmer blades, etc. Materials used for these applications include transformation-toughened zirconia, Al_2O_3 -SiCw, and Si_3N_4 -SiCw (Davis, 2001).

Aerospace

Most of the CMCs which are in developing stage for aero-structural applications, are using continuous fiber. However, attempts have been made for discontinuously reinforced CMCs. ZrB_2 platelet reinforced ZrC composite is one such example. It forms by reaction of Zr with B_4C powder in a graphite mould at about 1850–2000°C (Johnson *et al.*, 1989; Davis, 2001).

Composite with 3–12 vol% Zr has high flexural strengths of 800–900 MPa, Weibull moduli of 20–30, and fracture toughness of 12–15 (Claar *et al.*, 1989). Platelet toughening mechanisms leads to toughness values of 10–12 MPa with very low metal content. The increase in metal content increases the toughness in which ductile rupturing of metal ligaments during crack propagation also contributes. This composite has been successful even at very high temperature i.e., > 2700°C, definitely for a short time application like in rocket engines. The high refractory nature of the ZrB_2 and ZrC phases and the excellent thermal shock resistance of the composite has contributed to these excellent results. These materials have limited resistance to high-temperature oxidation and creep, hence, long term application is not feasible. These composites are also being under evaluation for prosthetic devices based on their strength, fracture toughness, wear resistance, and biocompatibility. Mechanical seals and other special wear parts are other prospective applications (Davis, 2001).

Space shuttle

Success of the space shuttle orbiter need development of a fully reusable thermal protection system (TPS) which should be capable of being used for up to 100 missions. During re-entry of the shuttle into the earth's atmosphere, surface goes up to 1260°C, where, tiles of ceramic are used. The nose tip and the wing leading edges, where reinforced C–C composites must be employed because it has to bear even higher temperature of 1650°C. The tile, coated with a high emittance layer of glass functions to dissipate heat and also acts as an insulator to block heat to the structure. The felt mounting pad i.e., the strain isolator pad (SIP) isolates the tile from the thermal and mechanical strains. The filler bar, also a nylon felt material coated with silicone rubber, protects the structure under the tile- to-tile gap from overheating. The substructure consists of aluminium alloys or graphite-epoxy composites (Korb *et al.*, 1981; Davis, 2001).

Heat-resistant

This CMC also uses direct metal oxidation to form composite of SiC particles in Al₂O₃ matrix. It has been used in high temperature components of furnace and heat exchanger. It uses very fine SiC particles and parent metal. Processing criterion is such that optimizes mechanical properties and high temperature stability. High temperature strengths tests have exhibited that holding at 1500°C even for thousand hours hardly affects properties (Davis, 2001). Continuous fiber ceramic composites (CFCCs) are the most recent advanced ceramic. The continuous fibers improves fracture toughness by overcoming brittle nature of the composite. The operative mechanisms to resolve the problem are namely, deflection and bridging of cracks through fibers and pull-out of fiber from the matrix. Though, the cracks may generate in the matrix, but the fibers continue to carry the load and avoid the catastrophic behaviour that is familiar in ceramic materials (Davis, 2001).

The most common matrix materials for CFCCs are SiC, Al₂O₃, Si₃N₄, mullite, and aluminosilicates and the fiber is SiC, although Al₂O₃ and carbon fibers are also used. Fiber may be as high as 35–50 vol%. The high-temperature stability, corrosion resistance, and toughness of CFCCs make them suitable for a wide range of applications in both the aerospace and industrial sectors (Craig, 1999; Wessel and Long, 2000; Effinger *et al.*, 2000; Davis, 2001). The major applications include:

Turbine engine components in which SiC–SiC and Al₂O₃–SiC composites industrial, and aeronautical engine applications. Radiant burner screens use SiC–SiC reverberatory screens for natural gas burners. Immersion heater tubes also use SiC–SiC composite burner tubes. The CFCC is not wetted or chemically attacked by the molten aluminium. Hot gas filters use Al₂O₃–Al₂O₃ composites in advanced coalfired energy applications. Turbine disks for rocket engines use integrally bladed disks for rocket engine turbopumps of carbon fiber reinforced SiC. Other potential applications for CFCCs include heat exchanger tubes, armor, pipe hangers for petroleum refining, submersible pump housings for chemical processing, etc.

Conclusion

Industrial use of composites started nearly fifty to sixty years back with very limited applications of polymer-based composites. With time it has gone far off in the form of variety as well as applications. Organic, metal and ceramic matrix composites are being used in almost all avenues of life due to tailorable capability. Though, comparing with organic and metal matrix composites, ceramic matrix composites have lesser applications due to brittle nature and limitations of processing routes. In time to come with innovative processing techniques, CMCs growth is likely to increase due to its high temperature capabilities.

Introduction

The issue of climate change has become a subject of intense worldwide interest. Previous studies showed that the most significant increase of energy consumptions and carbon dioxide (CO₂) emissions is taking place in cities, where rapidly expanding populations enjoy higher living standards and material affluence (Fong *et al.*, 2009; Sethi, 2015). Urban building system assumes significant environmental and ecological implications in terms of a contribution of emissions of CO₂ and other greenhouse gases (Atmaca and Atmaca, 2015). Thus, dealing with the issue of CO₂ emissions, it is vital to focus on reducing emissions from the cities. In spite of the fact that cities are the main sources of CO₂ emissions, presently there are still no specific measures directly addressing the global warming issue in the urban planning process. Urban trees are important components of the landscape and offer numerous benefits. Urban trees act as a sink for CO₂, helping to offset carbon emissions from urban areas by removing the greenhouse gas from the atmosphere through photosynthesis (Zheng *et al.*, 2013; Ren *et al.*, 2012). In order to effectively quantify CO₂ fluxes from urban forests, future research needs to integrate data from a combination of methodologies collected at a range of scales (Weissert *et al.*, 2014). Annual CO₂ exchanges are significantly different between sites, demonstrating the impacts of increasing urban density on the CO₂ flux to the atmosphere (Ward *et al.*, 2015).

The expansion of urban agriculture assists in reducing CO₂ emissions not only by producing food but also by reducing the amount of food transported from farming areas and therefore reducing the food mileage. The largest CO₂ reductions can be achieved by giving preference to the crops that are conventionally grown in energy intensive greenhouses or air-freighted before reaching the end-user (Kulak *et al.*, 2013). From the perspective of CO₂ reduction effects in the transportation sector, urban agriculture is expected to produce a considerable effect in diverse aspects such as the habituation of green growth, self-sufficiency, and food security (Lee *et al.*, 2015).

To evaluate the dynamic behaviors of the energy consumption and CO₂ emissions, a few of interdisciplinary studies have been conducted (Krey *et al.*, 2012; Chen *et al.*, 2012; Fang *et al.*, 2015). In study (Sun and Xu, 2016) was examined the carbon dioxide emissions and its influential factors through the proposed algorithm and the statistical method, providing a theoretical support for further measures to reduce emissions. The aim of the study (Russo *et al.*, 2015) was to develop a method to calculate carbon dioxide storage and sequestration at the streetscapes level using field data, an existing tree inventory and available region-specific allometric equations. Rich households generate more emissions per capita than poor households via both their direct energy consumption and their higher expenditure on goods and services that use energy as an intermediate input (Golley and Meng, 2012). The results revealed that human disturbance played the dominant role in influencing the carbon stock and density of forest patches close to the locations of human activities. In forest patches far away from the locations of human activities, natural forest regrowth was the dominant factor affecting carbon stock and density. Rapid urbanization increases carbon dioxide emissions both in the short-run and in the long-run (Sheng and Guo, 2016).

In this investigation adaptive neuro-fuzzy inference system (ANFIS) (Meng *et al.*, 2014) was used to detect the influence of population growth, urbanization, forest and agriculture land areas on the CO₂ emission prediction. The main goal is to estimate CO₂ emissions where there are lack of data. It can be challenge when developing inventory method for local communities, due to limited data. Therefore in this study the main aim is to detect which energy source has the most influence on the CO₂ emission prediction.

Methodology

Statistical Data and Study Area

Currently, the increased greenhouse gas concentrations in the atmosphere are one of the most pressing environmental problems. CO₂ is an important green-house gas and a major driver of climate change effects, as a result the predicted global temperature rise will be proportional to the total amount of CO₂ emitted. In recent years, increases in carbon dioxide concentrations are mostly due to rapidly increasing population energy use, and emissions from vehicular traffic. In fact, half of the world's population is living in cities and in Europe alone, it is estimated that around 70% of the EU population – approximately 350 million people live in urban agglomerations of more than 5000 inhabitants.

Table 1 shows inputs and output parameters which were used in this study. The dataset was taken from World Bank database for European Union countries. CO₂ emission is analyzed separately for solid fuel consumption.

ANFIS Methodology

Fuzzy inference system in MATLAB software is employed in the whole process of the ANFIS training and evaluation. In the process of identification of variables in the ANFIS architectures, the hybrid learning algorithms were applied. The functional signals progress until the 4th layer whereby the hybrid learning algorithm passes. Further, the consequent variables are found by the least squares estimation. In the backward pass, the error rates circulate backwards and the premise variables are synchronized through the gradient decline order.

Table 1 Input and output parameters

Inputs	Parameters description
Input 1	Rural population growth (annual %)
Input 2	Agricultural land (% of land area)
Input 3	Forest area (% of land area)
Input 4	Population growth (annual %)
Input 5	Urban population growth (annual %)
Output	CO ₂ emissions from solid fuel consumption (% of total)

**Fig. 1** Parameters influence on CO₂ emission prediction.**Table 2** Parameters influence on CO₂ emissions prediction from solid fuel consumption

Input 1	Input 2	Input 3	Input 4	Input 5
Input 1 trn=20.0839, chk=20.1240	trn=19.2803, chk=19.4741	trn=19.3473, chk=19.7549	trn=17.1679, chk=17.7554	trn=17.4268, chk=17.9994
Input 2	trn=20.0249, chk=20.0172	trn=16.6917, chk=16.7652	trn=17.4772, chk=17.7721	trn=16.6956, chk=16.9941
Input 3		trn=20.1805, chk=20.1998	trn=18.2306, chk=18.5132	trn=17.7790, chk=17.8881
Input 4			trn=18.4111, chk=18.7195	trn=17.3881, chk=18.6605
Input 5				trn=18.0497, chk=18.2643

Results

A searching procedure was performed in order to choose the inputs with the most impact and influence on the output parameters (CO₂ emission prediction). **Fig. 1** shows the urban population growth is the most influential parameter for CO₂ emission prediction from solid fuel consumption.

Table 2 shows the numerical results for all single parameters influence on the CO₂ emission prediction. Also the **Table 2** show the combinations of the two parameters influence on the CO₂ emission prediction. The bolded numbers represent the parameters with the highest influence on the CO₂ emission prediction. For example the combination of agricultural area and forest area form the most influential combination for the CO₂ emission prediction from the CO₂ emission prediction from solid fuel consumption. Generally the agricultural area is the most important parameter for the CO₂ emission prediction.

Conclusion

The global warming, mainly sourced from the human induced emission of CO₂, is one of the major environmental threats that we are facing in the 21st century. Therefore, this study aims at examining the relationship between rural population growth, urban population growth, population growth, agricultural land and forest area and CO₂ emission in European Union countries. Prediction of the future CO₂ emission is complex due to the many indicators and factors. Therefore in this study was proposed a new

approach to overcome the forecasting difficulties of the CO₂ prediction by removing some unnecessary input parameters. The main goal was to analyze the influence of different energy sources on the CO₂ prediction.

Results shown that for the CO₂ emission prediction from solid fuel consumption the most influential parameter is urban population growth.

Introduction

Energy is one of the most fundamental parts for any country and it is known as a strategic commodity. Any uncertainty about its supply can threaten the functioning of the economy, particularly in developing economies.

Energy services could be greatly improved by use of agricultural biomass in small-scale combustion units. Wood pellets are a reliable and proven fuel to be used in small-scale combustion units. However, these units should preferably be able to use different types of biomass depending what it is locally available. Therefore, studies have been focused on exploring the suitability of using agricultural residues for small-scale heat and power generation using direct combustion. Steam-treated pellets can help to address technical barriers that limit the uptake of pellets as a fuel for electricity generation, but there is limited understanding of the cost and environmental impacts of their production and use.

A modified Hartmann dust explosion tube was employed to determine the Minimum Explosible Concentration (MEC) and the flame speed for three Pakistani agricultural wastes: bagasse, rice husk and wheat straw (Saeed *et al.*, 2015) where it was shown the lean limits for these pulverized agricultural waste biomasses were comparable to that of pulverized wood but were much leaner than those for coal and hydrocarbon fuels, which indicate that these biomasses are highly reactive. In study (Cardozo *et al.*, 2014) was compared the combustion of different agricultural residues in a single unit designed for wood pellets. In study (McKechnie *et al.*, 2016) was investigated life cycle environmental (greenhouse gas (GHG) and air pollutant emissions) and financial implications of electricity generation from steam-treated pellets, including fuel cycle activities (biomass supply, pellet production, and combustion) and retrofit infrastructure to enable 100% pellet firing at a generating station that previously used coal. Impacts of retrofit infrastructure become increasingly significant at lower generating station capacity factors, further favoring steam-treated pellets for both environmental and financial metrics (McKechnie *et al.*, 2016). In study (Nilsson *et al.*, 2011), the costs and energy requirements for the production of pellets from agricultural raw materials were analyzed. The energy use in manufacturing pellets from air-dried crops was generally no higher than when moist sawdust was used as the raw material. The objective of work (Carvalho *et al.*, 2013) was to evaluate the technical and environmental performance of a 15 kW pellet boiler when operated with different pelletized biomass fuels, namely straw (*Triticum aestivum*), Miscanthus (*Miscanthus _ giganteus*), maize (*Zea mays*), wheat bran, vineyard pruning (from *Vitis vinifera*), hay, Sorghum (*Sorghum bicolor*) and wood (from *Picea abies*) with 5% rye flour. The investigation in the international market shows that mixed biomass pellets are promising fuels and with the appropriate support these fuels have many prospects for the future (Karkania *et al.*, 2012). The use of biomass pellets would not only create new market opportunities for agricultural industries, it would also reduce dependence on coal, as well as the greenhouse gas emissions associated with coal use (Karkania *et al.*, 2012). In paper (Tauro *et al.*, 2018) was examined the potential for biomass pellets to become a sizable low-carbon, renewable energy source that could compete with and substitute fossil fuels in specific economic sectors in Mexico where it was estimated that the market energy potential for pellets from currently available agricultural and forest residues in Mexico is between 131 and 233 PJ/yr, with total costs ranging from 6.3 to 12.8 USD/GJ. In paper (Dai *et al.*, 2015), a ceramic foam burner with embedded alumina pellets was designed, which set different shapes of tubes by taking can advantage of the discrete pellets. An experimental system was built to study the effects of the pellet diameter and pellet location on the combustion of low-concentration coal mine methane (LCM) (Dai *et al.*, 2015). Results indicates that the heat transfer features of 13-mm pellets are more similar to those of 10-PPI ceramic foam compared with 6-mm pellets and 9-mm pellets (Dai *et al.*, 2015). The combustion performance in a double-layer burner packed with alumina pellets of different diameters was experimentally studied in article (Gao *et al.*, 2012). In study (Qu and Feng, 2015), methane/air combustion in a two-zone catalytic alumina pileup-pellets burner with equivalence ratios varying from 0.55 to 0.70 was researched. Torrefied biomass has several benefits, such as higher energy density, good grindability, higher flowability and uniformity (Li *et al.*, 2012). The outlet of a mechanical biological treatment plant for mixed municipal solid waste is further processed to produce RRBf (Refined Renewable Biomass Fuel) within the frame of the EU Life project MARSS (Material Advanced Recovery Sustainable Systems) (Schulzke *et al.*, 2018). In paper (Dasappa *et al.*, 2004) addresses case studies of a low temperature and a high temperature industrial heat requirement being met using biomass gasification (Dasappa *et al.*, 2004). In paper (Verma *et al.*, 2017) provides a detail review on the need of drying of biomass before co-firing, different technologies used for biomass drying, biomass co-firing to the existing coal fired power plants and the environmental benefits of biomass co-firing. In paper (Hosier and Svenningsson, 1987) was presented the social and economic analysis of an evaluation of biomass briquettes as a substitute for charcoal.

Main cost in pelleting and briquetting are associated with expenditures related to feedstock provision and drying material. Innovative technology is proposed for producing the briquettes from wet biomass without the necessity for drying, thus reducing the overall price of produced briquettes.

Materials and Methods

Biomass Waste Management

According to the European Union standardization there are six procedures in the biomass waste treatment process:

1. Eco-design,
2. Biomass waste decreasing,
3. Biomass waste reusing,
4. Recycling and making compost,
5. Energy from biomass waste,
6. Biomass waste disposing.

In order to optimize the system for biomass waste management based on decreasing of pollution of life environment and for the cheapest solution there is goal to develop the biomass waste management process. This innovative solution could lead to revolution in the biomass waste issue. By entering of the main data for biomass waste, quantity and composition for the some region, the client could know which is the best solution for the biomass waste treatment and transport for the region. Several biomass waste treatments are included:

- Recycling,
- Combusting,
- Making compost,
- Performing anaerobic digestion and
- Disposing of biomass waste.

Fig. 1 The biomass treatment process flowchart.

Fig. 2 Process flowchart of the combustion plant with biomass.

There are several indicators which are calculated according to the input data. These indicators are:

- Global warming,
- Heavy metals emission,
- Nitrogen oxide emission,
- Smog formation,
- Water pollution.

Therefore the system has seven modules. These modules

- Calculation of emissions from collection and transport of biomass waste,
- Calculation of emissions from anaerobic digestion,
- Calculation of emissions from combustion,
- Calculation of emissions from recycled waste,
- Calculation of emissions from disposal,
- Calculation of emissions from compost,
- Calculation of cost benefit.

Burner for Agricultural Pellets

Fig. 3 Cherry pits briquettes.

Fig. 4 Coal powder pellets.

Fig. 5 Corn cob briquettes.

Fig. 6 Grape residues briquettes.

Fig. 7 Locust tree branches briquettes.

Main cost in pelleting and briquetting are associated with expenditures related to feedstock provision and drying material. Innovative technology is proposed for producing the briquettes from wet biomass without the necessity for drying, thus reducing the overall price of produced briquettes. Additionally, great number of innovative binders are proposed for compacting the biomass materials which are hard of impossible to bind together (rice husk, sunflower husks, grape seeds and residues, cherry and pitch pits etc.). [Figs. 3–11](#) shows the produced briquettes.

Fig. 8 Peach pit briquette.

Fig. 9 Rice husk briquettes.

Fig. 10 Sunflower husk pellets and briquettes.

Fig. 11 Wheat straw pellets.

Conclusion

The demand for biofuel has increased considerably in recent years, causing shortage of the traditional raw materials sawdust and wood shavings. Use of biomass fuels for electricity generation can simultaneously contribute to a number of common policy objectives, including: increasing the use of renewable energy; reducing greenhouse gas emissions; compliance with air pollutant emissions regulations; and encouraging economic development in communities dependent on agriculture and forestry sectors.

In this article innovative technology is proposed for producing the briquettes from wet biomass without the necessity for drying, thus reducing the overall price of produced briquettes.

Small-scale wood combustion systems have been well developed and reached a high quality and performance level. The energy efficiency has increased, the emissions have decreased, fully automatic operation systems have been developed and the combustion technology has been optimized for woody biomass fuels.

Treatment and Recycling of Domestic and Industrial Wastewater

Anne Morrissey, Dublin City University, Dublin, Ireland

© 2020 Elsevier Inc. All rights reserved.

Introduction

The availability of clean water is vital for life. With increasing human activity, droughts, floods and an overall reduction of new sources of fresh water, water pollution is becoming more common. Therefore, technologies for both protecting the water resources we do have and proper treatment and recycling of domestic and industrial wastewater are becoming essential. In the same way as processing any material, (in this case wastewater), there are a number of factors that need to be considered to ensure the material (ie the wastewater) is processed effectively so that the treated product is fit for purpose on completion. In the case of processing wastewater, the factors that need to be considered include:

- The quality of the source water (e.g., heavily polluted industrial wastewater, storm water, greywater, agricultural runoff, sewage etc).
- The quality of the treated water required to prevent pollution (e.g., for drinking, removal of pollutants from water before discharge to the environment, reuse etc).
- The treatment technologies available (primary, secondary, tertiary or quaternary) and therefore the types of materials required for the treatment of the water.
- The legislative requirements (can be country specific).

The focus of this article is on the treatment technologies and associated materials commonly used in the processing of wastewater. It is possible that some contaminants are incompletely degraded or removed by regular water and wastewater treatment, while other contaminants are discharged to water bodies directly from agricultural land field runoff and industrial sources without any treatment which could end up in drinking water sources (Fig. 1). This adds further complications to the water treatment process. To this end, there is a growing body of research on finding new materials as well as improving the performance of existing materials (such as activated carbon) to do this. Most of the applications of these emerging technologies such as nanotechnologies and advanced oxidation processes as well as those technologies using novel compounds such as graphene are in the tertiary/quaternary stage of wastewater treatment.

Management of Wastewater

Until the end of the third quarter of the 19th century, the main way for treating domestic and industrial wastewater was to simply move it from the place where it was generated out of population centres and into the nearest river or water body without any further treatment (Abellan, 2017). In certain parts of the world, especially in developing countries, this is still the case. In other countries, a lack of investment in adequate wastewater treatment infrastructure or poor maintenance of the infrastructure that does exist, means that partially treated wastewater can be discharged to the environment with the obvious resulting impacts on health, the environment and the supply of potable water. For example, figures from the World Health Organisation show that about 842,000 people die each year (globally) from diarrhoeal disease mainly caused by poor or no treatment of human wastewater, while at least 2 billion people use a drinking water source contaminated with faeces (WHO, 2018). While acknowledging that this is still a problem in certain parts of the world, the focus of this article is on how to successfully treat domestic and industrial

Fig. 1 Simplified Water and wastewater treatment cycle.

wastewater using the best available technologies most commonly used, thereby avoiding water pollution, health problems and water security issues. To this end, it is important to consider a number of technical questions in addition to the broader factors raised above before deciding on the best approach. These questions include, but are not limited to:

- Can the treated wastewater be disposed of directly to land, also known as on-site subsurface disposal, e.g., septic tanks or spray irrigation?
- Will secondary treatment of the wastewater (which can remove at least 85% of biodegradable products) be sufficient to avoid water pollution, or will some form of advanced treatment, such as ultra violet disinfection or advanced oxidation processes, be required?
- What method will be used to dispose of the treated sludge or biosolids? For example, is the level of pathogens in the sludge sufficiently low so that the treated sludge can be disposed of to land as a fertiliser without causing a pathogen problem in the food chain?

The above points will be described in more detail in the following sections as well as the materials required, particularly at the tertiary and quaternary treatment stages. In addition, using processed wastewater as a resource or material will be examined because if properly captured and treated, treated wastewater can be reused for irrigation and agriculture and the biosolids can be used as a fertiliser or treated by anaerobic digestion for the generation of biogas.

Wastewater Treatment

The processes involved in a typical wastewater treatment plant are shown in Fig. 2, and an aerial view of a wastewater treatment plant is shown in Fig. 3. The influent to a wastewater treatment works is made up of untreated domestic and industrial sewage as well as treated industrial wastewater which was not reused within the industrial plant itself and is below the standard permissible for direct discharge to surface waters. The steps of a wastewater treatment process are usually divided into preliminary, primary, secondary, tertiary and more recently quaternary. Large materials, such as paper, plastics and other large solids ranging in size from 5 or 6 mm and above depending on the specific facility, are removed in the *preliminary screening step*. This solid material is then washed, shredded in a *comminutor* and dewatered. The wastewater then passes through a centrifugal grit removal process, which removes coffee grinds, egg shells, sand and other relatively inert material. The material and grit are collected and sent to landfill for proper disposal, or used for road construction. The wastewater then flows by gravity to the *Primary Settling Tanks* which are also known as *clarifiers*.

Primary Treatment

Primary treatment is mainly a physical process to separate the solids in the wastewater from the liquid. Depending on local plant conditions and requirements, this step may also include fat, oils and grease removal, pH and temperature adjustment. These primary clarifiers, of which there should be at least two in a treatment works, can be circular or rectangular in shape. In some treatment plants, where space can be a problem, primary settling takes place in *Lamella Plate* settlement tanks in a tiered system, which are specially designed to maximise surface area for settlement, rather than in conventional settling tanks. The settled sludge is continuously scraped away for further treatment (Fig. 2), while the primary effluent (Liquid) is pumped to the secondary

Fig. 2 A modern sewage treatment plant showing wastes and products produced.

Fig. 3 Aerial view of a wastewater treatment plant, Canada (<https://www.saskatoon.ca/services-residents/power-water-sewer/sanitary-sewer/wastewater-treatment-plant>).

treatment stage. Scum from the top of the settling tanks is also pumped to the anaerobic digesters for further treatment. Primary treatment typically removes about 60% of the suspended solids and only 35% of the Biological Oxygen Demand (BOD) from wastewater, which is insufficient to meet most regulatory requirements. Hence the need for further treatment to remove those pollutants that did not settle in the primary clarifiers and the dissolved BOD that was not removed by physical treatment.

Secondary Treatment

Secondary Treatment is mainly an *aerobic biological* process. There are a large number of technologies that can be used depending on the size of the water treatment plant (single houses, small groups of houses, towns and cities), its location (near an aquifer, river, sea), the age of the treatment works etc. Two of the most common types of biological secondary wastewater treatment are the relatively newer *suspended growth systems* such as Activated Sludge (AS) and the older, more stable *fixed growth systems*, such as Trickling Filters, (TF) (also known as biofilters, trickle biofilter and biological filter among other variations) and constructed wetlands. Both suspended and fixed growth systems work in the same way by using microbes to “eat” the organic matter in the sewage. The difference between the systems is that the microbes in the AS system are suspended in the water, whereas in the TF systems, the microbes are fixed to a substrate such as crushed rock, corrugated plastic, coke or sand with the wastewater flowing over the surface to provide contact with the organic material. Both AS and TF systems are still being used, and the choice of which to use in a particular situation depends on factors such as cost, location, availability of space, sludge management requirements etc. A brief description of each is given below and further details on these technologies can be found in any number of books on wastewater treatment such as Metcalf and Eddy Inc. *et al.* (2014) and Nathanson and Schneider (2015).

The *Activated Sludge* process uses an aeration tank containing the primary treated sewage combined with microorganisms, (mainly saprotrophic bacteria and some protozoa) that degrade the organics or carbonaceous material in the wastewater (Fig. 4(a)). The diffused air also has the effect of thoroughly mixing the microorganisms and wastewater together to ensure consistency in the tanks. At the same time, the microorganisms grow in conglomerates or *flocs*, (Activated Sludge), which combined with the wastewater is known as *mixed liquor*. After about 6 h of aeration (depending on the system), the mixed liquor flows to *secondary clarifiers* where the flocs settle to the bottom of the tank and are either removed as excess sludge (about 70% of the AS) or re-circulated back into the aeration tank (about 30% of the AS). This sludge is called Activated because the microorganisms are acclimated to the wastewater and will continue to absorb and metabolise fresh sewage; hence this process can be maintained continuously without the addition of fresh microbes. The excess sludge is processed further, along with the primary sludge, in the anaerobic digesters (Fig. 2). The supernatant from the settling tank can be discharged to surface waters (river, lakes or sea) without further treatment or can be processed further in a tertiary treatment step where nutrients and/or micro-pollutants are removed. In poorly managed activated sludge systems, a range of *mucilaginous filamentous bacteria* can develop which produces a sludge that is difficult to settle and which can flow into the secondary clarifiers contaminating the final effluent quality.

A *Trickling Filter* (TF) type system is usually circular in shape, about 2 m deep and 50–60 m in diameter (Fig. 4(b)). Sometimes the TFs are covered for odour and/or temperature control, as the efficiency of a TF system is reduced in cold weather. The effluent from the primary clarifiers is sprayed over the surface of the filter bed by a rotating distributor arm (Fig. 4(b)). The filter medium

Fig. 4 (a) Aeration tank in a wastewater treatment plant (By SuSanA Secretariat [CC BY 2.0 (<http://creativecommons.org/licenses/by/2.0>)], via Wikimedia Commons) (b) Schematic of Trickling Filter plant system (not to scale).

used should have a very high surface area to volume to maximise the opportunity for biological growth while at the same time, porous enough to allow the air to circulate. As the primary effluent flows through the filter medium, a biological slime (also called a *biofilm*) starts to grow and thicken. The microorganisms in the biofilm absorb the dissolved organic compounds in the effluent being treated, thus lowering the BOD of the wastewater. As the microorganisms multiply, the biofilm thickens until a point where the flowing wastewater *sloughs* i.e., washes off the biofilms from the surfaces of the filter medium. This water containing the sloughed off biofilm trickles by gravity to the bottom of the filter and is collected in underdrains for discharge to a secondary clarifier. The biofilm containing the microorganisms is allowed to settle out in the clarifier, which is collected and sent to an anaerobic digester for further treatment. The air being circulated through the filter medium provides oxygen for the stabilisation of the organics, with the release of carbon dioxide, water and other products. Some of the treated water may be pumped back into the trickling filter inlet for a second pass through the filter medium for two reasons: (a) As a means of keeping the flowrate constant through the trickling filter and (b) to improve the pollutant removal efficiency.

Both secondary treatment methods described above produce sludge as a by-product that needs to be treated further before final discharge, in order to reduce its volume, stabilise it and ensure that there are no pathogens left in the digested sludge. The main sludge treatment process used is *Anaerobic Digestion (AD)* followed by pasteurisation or thermal drying to remove all pathogens. This process can provide useful products in the form of biogas (which can be used to generate energy as it typically contains 55%–75% methane) and nutrient rich biosolids which can be used as a fertiliser. Further details on the anaerobic digestion process can be found in many sources such as Caruana and Olsen (2012).

While the Trickling Filter and Activated Sludge systems are the most commonly used secondary treatment systems, there are a number of other processes in use particularly for smaller scale or rural communities. Of these, Biodiscs also known as rotating biological contactors (a fixed growth system) and the wastewater treatment pond or constructed wetlands (a suspended growth system) are the most commonly used. A *rotating biological contactor (RBC)* system consists of packs of closely spaced, parallel discs (known as media and typically made from polyethylene or PVC) on a rotating shaft, on which the microorganisms grow. As the shaft rotates, the discs are alternately submerged in wastewater and then exposed to the atmosphere above the liquid, allowing a layer of biofilm to grow on each disc. The microbes contained in the biofilm biodegrade the pollutants in the wastewater in a process similar to the TF system. There is no need to recycle the sludge in a RBC system but a secondary clarifier is needed where the sloughed off sludge can settle.

A *wastewater treatment pond system* is a low cost, energy efficient, natural water purification system and is usually used in rural areas where land is available. Typically, about one hectare of land is needed to treat the wastewater generate by 1000 people. There are many types of ponds depending on whether they are aerobic, anaerobic or a mixture such as in a *Facultative lagoon* (Fig. 5). The general approach to the operation of a treatment pond system is that the wastewater to be treated is held in a depression or pond in the ground, and through a combination of microbes, sunlight and oxygen, the biological pollutants in the water are degraded. The bacteria degrade the pollutants in the wastewater producing carbon dioxide, methane (if anaerobic) and other compounds such as ammonia and hydrogen sulphide. These compounds are then degraded by algae contained in the pond, as they consume the compounds released by the bacteria to produce oxygen, which is then used by the aerobic bacteria to further decompose the pollutants in the wastewater. It should be noted that a problem can arise, particularly in warm weather, if the algae grow too much and are carried out in the effluent, thereby exceeding the allowable suspended solids limits in the effluent from secondary treatment. This problem can be eliminated with the construction of a number of ponds in series to control the flow of the effluent.

Tertiary Treatment

The wastewater treatment industry today is moving towards high added value resource recovery, from waste and wastewater, offering new technological options and opportunities to address modern societies and to protect the environment

Fig. 5 Schematic of a Facultative Lagoon as an example of a wastewater stabilisation pond.

(Curl *et al.*, 2014; Moustakas *et al.*, 2018). As seen above, secondary treatment can only remove about 85% of the BOD and TSS and 30% of the phosphorus from the sewage. In addition, pharmaceutical residues, personal care products (PCPs) and antibiotics that are being used in increasing amounts, are not removed by traditional water treatment systems and are entering waterways in volumes not seen in the past (Gholamvand, 2015). Furthermore, the more prevalent use of antibiotics has resulted in their presence in increasing concentrations within activated sludge systems, resulting in a rise of antibiotic resistant bacteria and their spread into the environment through the water course (Wang and Wang, 2016). As a result, tertiary treatment that can remove up to 99% of pollutants, including bacteria, from raw sewage and is becoming the norm. While the cost of doing so can be as much as the cost of secondary treatment, tertiary treatment is being increasingly applied in developed countries due to increasingly stringent water quality standards.

The most common type of tertiary treatment is *disinfection*, either by chlorination or with Ultra Violet (UV) light, which kills off any remaining pathogens in the water. In some wastewater treatment plants, this is the only form of tertiary treatment present and may or may not be used all the time. Disinfection is particularly important if the treated water is being discharged to an area in the sea frequented by swimmers, where shellfish and other microorganisms live or where sources of drinking water supplies may be contaminated by wastewater effluent. *Chlorination* is the more common process of the two and is known to be effective in destroying a variety of bacteria, viruses and protozoa, including *Salmonella*, *Shigella* and *Vibrio cholera*. The concentration of chlorine supplied must be tightly controlled: It should be sufficient enough to kill off any pathogens, but not too much to cause an adverse environmental impact, such as fish kills. To avoid problems with chlorination, newer wastewater treatment plants use Ultraviolet light rather than chlorine for disinfection. The UV light kills any pathogens by blocking the DNA required for cell division and can kill up to 99.99% of any remaining pathogens. At the same time undesirable by-products such as Trihalomethanes, a by-product of chlorination, are less likely to be produced and the quality of water remains unchanged. The addition of an effluent filter (Fig. 2) upstream of UV in a tertiary treatment process is an optional additional process to improve water quality to a standard sufficient for water reclamation or reuse.

Other situations where tertiary or advanced treatment is required are in situations where there is insufficient removal of nitrogen and phosphorus in the secondary treatment to prevent *eutrophication*, *algal blooms* and other environmental problems. Secondary treatment is usually only effective in removing Carbonaceous BOD and additional treatment is needed to remove Nitrogenous BOD. Furthermore, nitrogen in sewage effluent is mostly present in the form of ammonia compounds, which are not only toxic to fish in high concentrations but which can cause *nitrification*. Finally, both nitrogen (Ergas and Aponte-Morales, 2014) and phosphorus (Goel and Motlagh, 2014) are valuable resources known as macronutrients and the recovery of these from wastewater is becoming increasingly important.

Phosphorus in sewage is present as organic phosphorus or phosphate and can be removed in two ways. One is a physical-chemical process using a precipitating agent such as Aluminium Sulphate (Al_2SO_4) also known as alum, Ferric Chloride, FeCl_3 or Calcium Oxide (CaO) to the sewage. In the precipitation method, the cation in the agent reacts with the phosphorous ions in the sewage to form an insoluble precipitate, which then forms a floc and settles to the bottom of the clarifier. The precipitating agent or coagulant can be added at any point in the treatment process (e.g., after primary settling or after secondary treatment), but if added after secondary treatment, additional settling tanks and filters are required, thereby increasing the quantity of sludge generated. However, in line with making wastewater treatment plants more sustainable, the phosphorus contained in the sludge can be extracted (Egle *et al.*, 2016; Cieřlik and Konieczka, 2017).

The second method for removing phosphorus from wastewater is through modifying the activated sludge process so that it operates as an enhanced biological phosphorus removal (EBPR)- activated sludge plant (Goel and Motlagh, 2014). In an EBPR process, heterotrophic bacteria, called polyphosphate-accumulating organisms (PAO) not only consume phosphorus as food, but also accumulate large quantities of polyphosphate within their cells thereby enhancing the removal of phosphorus from the wastewater. This biomass settles out in the sludge from which the phosphorus can be removed.

The most common method to remove nitrogen from sewage is to use a biological nitrification-denitrification process. A schematic of the process is shown in Fig. 6, and an animated description of the process can be found at website provided in “Relevant Websites section”. In the nitrification step of this process, the ammonia nitrogen (either NH_3 or NH_4^+ , depending on the pH of the system) is converted to nitrite (NO_2^-) and then to nitrate (NO_3^-) by nitrifying or autotroph bacteria such as *Nitrosomonas* and aeration. As the nitrogen is still present in the water, it can be removed by the addition of denitrifying or heterotroph bacteria such as *Pseudomonas* to the sewage and methanol as a source of food for the bacteria. It is crucial to keep conditions in the tank anoxic, otherwise, the bacteria will use the dissolved oxygen in the water instead of the nitrate oxygen in their metabolic process. One product of the process is molecular nitrogen which escapes into the atmosphere as a gas.

Quaternary Treatment

Pharmaceuticals are designed so that they are chemically stable and they have a biological effect on many cells and organisms. As a result, excreted or unused pharmaceuticals can be persistently present in the environment and act as a contaminant with hazardous effect on living organisms (Joss *et al.*, 2005). Furthermore, the removal of pharmaceuticals and other emerging pollutants from the wastewater is more difficult due to their small molecule size, persistence and a lack of knowledge of what exactly is in any specific wastewater stream (Byrne *et al.*, 2017; Sweetman *et al.*, 2017). As a result, even more advanced treatment is required to achieve this. These advanced treatments include physio-chemical treatments such as biodegradation, adsorption to activated carbon, air stripping, incineration, ion-exchange, reverse osmosis, coagulation-precipitation, membrane separation and oxidation reactions including thermal and catalytic oxidation, oxidation by permanganate, chlorine, ozone and hydrogen peroxide (Gholamvand, 2015). While not normally used for wastewater treatment, some of these are becoming more commonly used at the quaternary treatment stage to remove emerging pollutants. This is an additional step following mechanical removal of solids (primary treatment), using microorganisms to degrade organic matter (secondary treatment) and disinfection, phosphorus and nitrate removal (tertiary treatment). Nevertheless, each of the advanced treatment processes has shortcomings and is not fully effective at removing these persistent pollutants completely (Gholamvand, 2015). For example, the air stripping process, which is commonly used for the removal of volatile organic compounds for aqueous media, merely transfers the pollutants from liquid phase to gaseous phase rather than destroying them completely. In the process of adsorption to activated carbon, the spent carbon must be either regenerated or incinerated, which converts the adsorbed pollutant to by-products, which may be worse for the environment than the original compound. Membranes such as those used for reverse osmosis, nanofiltration and ultrafiltration can be an effective method for the removal of both potential pathogens and chemical contaminants, but

Fig. 6 Biological Nitrification – Denitrification process in wastewater treatment.

filtration systems are susceptible to fouling and do not make the microorganisms inactive. Chlorination and ozonation are two water disinfection and destructive oxidation technologies in water treatment process, but as seen earlier, chlorine-based water disinfection processes may form potentially toxic and carcinogenic disinfection by-products (DBPs) such as trihalomethanes.

As a result of these shortcomings, there is a growing area of research to find new ways to ensure that the discharged wastewater is properly treated to the standard required, particularly if the water is to be reused. One such quaternary process is *Advanced Oxidation Processes* or AOPs. Advanced Oxidation Processes rely mainly on the formation of short-lived oxygen containing intermediates, non-selective reagents, such as hydroxyl radicals ($\text{OH}^\bullet$) or superoxides ($\text{O}_2^{\bullet-}$). These are produced, separately or in combination, with the help of strong oxidising agents such as ozone or hydrogen peroxide, irradiation, such as UV light and a catalyst such as titanium dioxide, which then react unselectively with contaminants, such as pesticides and pharmaceutical molecules, to form smaller inorganic molecules. While the goal of the oxidation of compounds is complete mineralization to carbon dioxide and water if the treatment time is sufficient, it is usually not necessary to operate the processes for this long and therefore the target pollutants are usually degraded to biodegradable intermediates. The chemical reactions involved are essentially the same as if the pollutants were slowly oxidised in the environment, but the oxidation rate is considerably faster (Gholamvand, 2015). The main advantage of AOPs over chemical and biological processes is that they neither transfer pollutants from one phase to the other (as in chemical precipitation, adsorption and volatilization) nor produce massive amounts of hazardous sludge (as in activated sludge processes) and hence have a lesser impact on the environment (Deng and Zhao, 2015). Titanium dioxide (TiO_2) is the most popular photocatalyst due to its low cost, nontoxicity and high oxidising ability, even though there has also been considerable research into other photocatalysts such as ZnO , ZnS , perovskites, Semiconductor-Graphene composites, MoS_2 , WO_3 and Fe_2O_3 . Moreover, titania photocatalysts can easily be immobilized on various surfaces and be scaled up for large scale water treatment (Byrne *et al.*, 2017).

The oxidation potential of various oxidising agents is compared in Table 1, while the most common AOPs developed for wastewater treatment are presented in Table 2. Some of these, such as photolysis have been commercialised, while others (such as photocatalysis and ultrasound) are still at the lab or prototype stage. Processes that are at a more advanced stage of development and which have been used at full scale include combinations of H_2O_2 , O_3 and UV, Fenton's reagent, super-critical water oxidation and ionizing radiation. The focus of the remainder of this section of this article is on the most common classes of materials used in quaternary treatment of wastewater, which include adsorbents, photocatalysts and oxidising agents.

Classes of Materials Used in Wastewater Treatment

Adsorbents

Adsorption is the most common physical process for quaternary treatment to remove trace organic compounds from water (Wang and Wang, 2016). One of the most commonly used adsorbents in wastewater treatment is *Activated Carbon* which is usually made from the pyrolysis and chemical treatment of an organic material such as coal, coconut shells and wood. AC is typically used in granular form (GAC) in a packed or adsorption bed following the activated sludge step, but sometimes as a powdered feed (PAC) to remove odours and taste. Other carbon based adsorbents such as Graphene and carbon nanotubes are being widely researched in order to enhance the adsorption capacity for the micro pollutants. The advantages of adsorption especially, by activated carbon, is the simplicity and applicability for wide range of compounds, but the removal efficiency of each compound depends on different parameters such as solubility, $\text{P}k_{\text{a}}$, chemical properties of the compound, acidity, porosity, chemistry and surface properties of the adsorbent and operating parameters such as contact time (Wang and Wang, 2016). However, for efficient performance, regular regeneration of the carbon is required which is expensive. In the case of PAC, the long contact times and possible need for a batch system/coagulation and in separating the powdered carbon from the water also adds to system

Table 1 Comparison of oxidising potential of various oxidising agents

Oxidising species	EOP (V)	EOP relative to chlorine
Positively charged hole on TiO_2	3.20	2.35
Fluorine	3.06	2.25
Hydroxyl radical	2.80	2.06
Atomic oxygen	2.42	1.78
Ozone	2.08	1.52
Hydrogen peroxide	1.78	1.30
Chlorine	1.36	1.00
Oxygen (molecular)	1.23	0.90

complexity. Furthermore, dissolved organic compounds, surfactants and humic acids compete with binding sites of the activated carbon and can block pores within the AC structure. In addition, during chemical regeneration, adsorbed compounds are released to a regenerating medium that will have to be disposed of in landfill or released to the air in the form of CO₂ during incineration.

One way that is widely researched to improve the performance of Activated Carbon is to incorporate specific chemical functionality onto the AC surface, e.g., to target specific pollutants (Sweetman *et al.*, 2017), with the addition of a photocatalyst such as Titanium Dioxide. Composites based on activated carbon and titanium dioxide are a new material in their own right, known as Integrated Photocatalysts (IPCA). Another way to improve the performance of Activated Carbon is to improve the AC regeneration techniques, by using electrochemical regeneration rather than thermal regeneration, which was first studied by Narbaitz and Cen in 1994 (Narbaitz and Cen, 1994). Finally, there is a growing body of research on developing new materials for water treatment, the most promising of which are advanced nanomaterials including graphene, carbon nanotubes (CNTs), and composite materials.

Most research to date in relation to the removal efficiencies of *Graphene and Graphene Oxide* has been completed at laboratory scale using synthetic water (Wang and Wang, 2016), with very few commercial applications for water treatment reported so far. Nevertheless, graphene and its precursor graphene oxide are showing promise for use in water treatment due to the relatively low quantity of these materials required to achieve high adsorption or filtration capacity and easier regeneration of the graphene based materials compared to activated carbon (Sweetman *et al.*, 2017). Recent lab-based research has also shown that porous graphene nanosheets (Tabish *et al.*, 2018) and membranes made from graphene oxide (GO) (Abraham *et al.*, 2017), rather than pristine Graphene which is hydrophobic, allow water to permeate, while at the same time blocking materials like gases and solvents. This makes them ideal candidate materials for water treatment. Scaling up this technology for commercial applications remains the challenge. While a separate issue, an additional concern is the fate of wastes that contain these nanomaterials that enter the wastewater treatment system is that while they can be removed from the water if quaternary treatment is used, they will end up in the sludge (Suárez-Iglesias *et al.*, 2017). It was also noted that graphene oxide has a negative effect on the biological treatment in the activated sludge process due to the biocidal ability of graphene materials (McGlade, 2017). So, on the one hand, graphene related materials have the potential to greatly improve the quality and the efficiency of water treatment particularly if used as a tertiary or quaternary treatment, while on the other hand, cause their own problems by entering the sewage system as nanomaterials from the environment.

Photocatalysts

The most common photocatalyst used as part of an Advanced Oxidation Process (AOP) is Titanium Dioxide (Byrne *et al.*, 2017). Titanium Dioxide is the naturally occurring oxide of titanium, with its use as a white pigment being its most widely used application. The TiO₂ crystal structure can occur in several polymorphs: Anatase, rutile, brookite and TiO₂ (B), with the rutile and anatase phases being of most use commercially. As the rutile form is the most stable and the anatase form is the most photoactive, commercially available TiO₂ used for photocatalysis usually contains a mixture of the two forms. For example, Evonik (Degussa) P25 contains ~80% anatase and ~20% rutile and is often used as a reference to which the performance of other photocatalysts are compared (Pelaez *et al.*, 2012; Byrne *et al.*, 2017). The photocatalytic properties of titanium dioxide were first published in 1972 (Fujishima and Honda, 1972), with the original research focussing on water splitting using an electrochemical photocell with TiO₂ and platinum electrodes. Since Carey *et al.* (1976) first reported the photocatalytic degradation of organic molecules (biphenyl and chlorobiphenyl derivatives) numerous works have been published demonstrating the efficiency of the use of TiO₂ in photocatalytic processes as a mean of wastewater detoxification (Deegan, 2011). Titanium Dioxide has the potential to mineralize pollutants, including pesticides, pharmaceuticals and other organic chemicals in water for drinking and industrial

purposes, without generating a waste disposal problem (Byrne *et al.*, 2017). Further advantages of TiO_2 include its very high photoactivity compared to alternatives (Table 1), stability, chemical inertness and relatively low cost. However, the full commercial application of TiO_2 mediated photoreactions is subject to a series of technical challenges including:

- TiO_2 is a nanoparticle powder and therefore the successful separation of the TiO_2 catalyst after water treatment is considered a major obstacle. In addition, its presence in the treated water stream after the photocatalytic degradation can cause genotoxicity and cytotoxicity to aquatic and human lives (Srikanth *et al.*, 2017).
- TiO_2 as a catalyst works best in the UV light range, which greatly adds to the cost of treatment.
- The photocatalytic efficiency of the TiO_2 catalyst is poor at low concentration of pollutants.

To overcome these shortcomings, much research is ongoing to find ways to immobilise TiO_2 (Gholamvand, 2015; Byrne *et al.*, 2017; Srikanth *et al.*, 2017), doping TiO_2 with a metal such as Zinc, or non-metals such as Nitrogen, to bring the working range of TiO_2 into the visible range to create Visible Light Active TiO_2 (VLA- TiO_2) (Pelaez *et al.*, 2012) and the development of a new class of TiO_2 catalyst combined with an efficient adsorbent (Gholamvand, 2015). TiO_2 has been immobilised on numerous surfaces including glass and stainless steel (Byrne *et al.*, 2017), adsorbents such as activated carbon or zeolites, also known as Integrated Photocatalytic Adsorbents, or IPCAs (Basha *et al.*, 2015) and blends of Graphene Oxide/ TiO_2 nanocomposite and polysulfone (Kumar *et al.*, 2016). Most research is still at laboratory or pilot scale using synthetic water, with no commercial applications reported to date. Whatever immobilised photocatalyst is developed will need to be photoactive in the visible light range and also be recycled many times without significant loss in its photocatalytic activity (Srikanth *et al.*, 2017). In all cases, an effective assessment of these nanomaterials is needed to address several issues regarding test protocols, ensure true photocatalytic activity, and explore future commercialisation of the materials (Pelaez *et al.*, 2012).

In addition to TiO_2 photocatalysis, photo-Fenton is another popular photochemical advanced oxidation process. Fenton's chemistry involves reactions of hydrogen peroxide in the presence of iron to generate hydroxyl radicals. Ultraviolet light enhances this generation by the photo reduction of Fe(III) to Fe(II) . Since iron is abundant and non-toxic and Fenton's reactions operate at room temperature and normal pressure, it is seen as a viable option for wastewater treatment. However, the strong dependence on the aqueous solution pH (optimum pH 2–4 for the production of OH radicals) and on the concentrations of hydrogen peroxide and ferric/ferrous ions and the disposal of the iron sludge are factors that have limited its commercialisation to date.

Sludge Management

The discussion in this paper so far has been on the treatment of the aqueous stream of the wastewater to ensure that when the treated wastewater is discharged to the environment, it meets national standards with minimal impact on the environment. However, in treating the water, the removed contaminants have to go somewhere and usually end up in a sludge in a more concentrated form than in the original untreated wastewater. As a result, the sludge must be treated properly to avoid any environmental problem; otherwise, the original treatment processes are pointless (Dentel and Qi, 2014). The costs of sludge management can be up to 50% of the cost of wastewater treatment (Nathanson and Schneider, 2015), but some of these costs can be recovered, e.g., by using the treated sewage sludge as a fertiliser or recovering the energy from the sludge through anaerobic digestion. As a result of this, sludges are more generally referred to as biosolids to emphasise its potential as a natural resource (Nathanson and Schneider, 2015).

The treatment of the biosolids is complicated by the fact that their composition depends on the composition of the original wastewater, which can vary considerably, leading to a wide variation in sludge characteristics. A typical wastewater sludge will contain organics, microbes, nutrients and a wide variety of household chemicals and pharmaceuticals. Indeed, it is likely that a typical sludge will also contain illicit drugs as well (Yadav *et al.*, 2017), as very little is known about the environmental fate and toxicity of these drugs. The amount of sludge generated depends on the type of treatment provided and on the amounts of chemicals added. Primary sludge from the primary settling tanks (Fig. 2) typically has a solids concentration of about 7%, which can go septic and odorous if not properly handled, while the sludge from the activated sludge tanks containing about 2% solids or less. Therefore, the main objectives of sewage sludge treatment are volume reduction and stabilisation of organics prior to disposal. Several processes are typically used for these purposes including gravity belt thickeners, anaerobic digesters, sludge dewatering and sludge drying with nutrient recovery (Fig. 2). Alternatives to anaerobic digestion include incinerating or composting the sludge with municipal waste, following a dewatering process.

The main purpose of sludge dewatering and thickening is to increase the solids concentration in the sludge; otherwise the sludge is very difficult to manage. Sludge Thickening is a physical process that is usually carried out using a Gravity Thickener, Dissolved air Floatation (DAF) or centrifuge, in which sludges can be thickened to more than 10% solids, thereby reducing the sludge volume by half or more. This process is used before or after the dewatering process, and/or before or after digestion on any of the sludges generated in the WTP. Details on how the process works can be found in any number of text books (for example, Metcalf and Eddy Inc *et al.*, 2014), or on various websites such as provided in "Relevant Websites section" or "Relevant Websites section"

The next step in the process is sludge digestion in which biochemical decomposition of the sludge occurs, converting the organics into simpler more stable substances, reducing the total mass of the sludge solids and destroying pathogens. In most

wastewater treatment plants, digestion is carried out anaerobically with the production of a biogas (a mixture of methane, carbon dioxide and other gases), which helps make the wastewater treatment plant energy neutral. The biochemical reactions that take place during the anaerobic digestion process are quite complex, starting with the breaking down of insoluble organic polymers into soluble derivatives such as sugars and amino acids with one set of bacteria and then further decomposition of these chemicals into carbon dioxide, hydrogen and organic acids, with a second set of bacteria. These organic acids are converted into acetic acid and gases such as ammonia, hydrogen and carbon dioxide and finally, another set of bacteria convert these products into methane and carbon dioxide. The quantity of methane produced is an indicator of how well the plant is operating and is tightly monitored. Typical detention times are between 15 and 40 days depending on the characteristics of the sludge.

In sludge dewatering, the sludge is dewatered or dried to the consistency of moist earth. Even though this dewatered sludge can contain as much as 70% moisture, it now appears more akin to a solid than a liquid and so is easier to handle. This process typically takes place using a sludge drying bed if there is enough land on which to spread the sludge or with a vacuum filter, centrifuge or belt press filter, if not. Further details on the process can be found in any text book on wastewater management, such as the previously mentioned [Metcalf and Eddy Inc. et al. \(2014\)](#) or [Nathanson and Schneider \(2015\)](#).

The final step in the process is sludge disposal, which can range from dumping in the sea, landfilling, incineration or sale as a fertiliser. In most developed countries, dumping sludge at sea is no longer permitted, while landfill disposal is severely restricted. Therefore, the two most commonly used routes for disposal are thermal treatment and land application. Thermal treatment is an expensive option, because the exhaust from the incinerator must be scrubbed to remove pollutants to adhere to the relevant national "Clean Air Acts" and so is really only an option where the land disposal is not available. Therefore, the most sustainable option is to use the treated sludge (biosolids) as a fertiliser, if properly treated to standards ([DELG, 1999](#)) as it can contain large amounts of nitrates and phosphates. The sludge can be applied as ground cover or mixed into the ground during placement. Liquid digested sludge in the form of a slurry, can be spread directly onto land, but only at certain times of the year. In the EU, the application of treated municipal sewage sludge to agricultural land is governed by EU Directive 86/278/EEC ([EU, 1986](#)), which requires that sewage sludge undergoes biological, chemical or heat treatment, long-term storage, or any other process to reduce the potential for health hazards associated with its use.

Wastewater Recycling and Reuse

As noted in the Introduction, due to increasing human activity, droughts, floods and an overall reduction of new sources of fresh water, water is becoming a limited resource. Water recycling and reuse of treated wastewater for applications such as agricultural irrigation and street cleaning, or for household uses like toilet flushing and watering lawns are becoming more common. In many countries, reuse of treated wastewater has been proven as a reliable alternative water resource and an effective solution for coping with water scarcity conditions.

Of the two types of domestic wastewater, greywater is easier to recycle than blackwater. If Greywater (wastewater produced from showers, baths and washing machines) is collected separately to Blackwater, (wastewater generated from toilets, kitchen sinks and dishwashers), it could be reused for watering gardens, washing cars or flushing toilets. While the reuse of greywater within a household is becoming more common, its rollout is hindered by the relatively high cost of the systems especially if retro-fitting, the need for careful maintenance of the system and concerns that the quality of the water may pose a health risk. A more sustainable and cost effective approach, is to reduce water usage by fitting more water efficient appliances and changing habits than going to the expense with possible operational complications of recycling greywater within a household.

Reusing Blackwater within a home is not possible and must be sent for biological or chemical treatment and disinfection in a wastewater treatment plant before reuse or treated on site in a septic tank arrangement, for example. Once treated to a sufficient standard, treated effluent can be, and is being reused all over the world as in the "toilet to tap" initiatives. As a result of growing populations and drought, recycled water is being incorporated into the water supply in places such as Singapore, California and Australia and is slowly gaining acceptance. However, the biggest problem will be for people to accept that the treated water is not only potable, but can sometimes contain less contaminants than raw water. This is an ongoing challenge, and not only is recycling water becoming a necessity, a sustainable water future will demand it.

Conclusions

Treating wastewater to the standard required for discharge to the environment is becoming increasingly expensive and more complex, with tertiary treatment and in a growing number of situations, quaternary treatment, becoming the norm. However, if wastewater is being treated to almost potable standards, then the onus is on society to recycle and reuse this water as is the case for any scarce resource and not to discharge it to the environment as a waste product. One of the main limiting factors of reusing water is the concern that it could be contaminated or could cause a public health issue, and so policies will need to be put in place to ensure that this is not the case as well as promoting water conservation.

Unified Modeling Language for Cooking Oil Management

Dalibor Petković, University of Niš, Pedagogical Faculty in Vranje, Partizanska, Vranje, Serbia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Biodiesel is considered to be a good alternative in renewable energy generation. Therefore it is well studied throughout for its efficient, economic and greener production. Biodiesel production stands out on an international level because of its environmentally sustainable characteristics and the potential to promote rural development in developing countries. Introducing waste cooking oil into the biodiesel chain holds the potential to promote social inclusion in urban areas in all countries.

There is a need for recyclers to convince the food establishments and users of cooking oil of the benefits of recycling cooking oil, which in turn obtains a steady source of waste cooking oil as feedstock for biodiesel production. In addition, as the biodiesel life cycle defined is very much dependent on waste cooking oil as a feedstock, it is recommended to optimize the waste cooking oil collection network.

In this article we recommend research into the collection of waste cooking oil, such as a pilot-scaled collection and production scheme in large estates. The government should provide outlets for biodiesel, for instance electricity in estates or a subsidy for drivers choosing to use environmentally friendly biodiesel as fuel. For such a purpose we modelled a waste cooking oil management software which will help in the collection of waste cooking oil. Biodiesel is conventionally produced by alkaline-catalyzed transesterification, which requires high-purity oils. However, low-quality oils can be used as feedstocks for the production of biodiesel by enzyme-catalyzed reactions.

Therefore it is essential to model an waste cooking oil management software which will be acceptable for all users in the process of the waste cooking oil management. Moreover it is more important the software would be universal and can be applied in all suppliers and all collectors of the waste cooking oil. Also the software should be understandable and easy in application for anyone. In order to make such a software it is important to analyze and model the structural and dynamical characteristics of the software. One of the best solution for analyzing and modeling of the software is object-orientated approach (Lethbridge and Laganier, 2005). This approach is used at the beginning of the software life cycle (Jacobson, 1993).

The object-orientated strategy is focused on assembly of the system from a library of reusable objects. By assembling the objects the useful computer application could be made which represents one system. Although there are different methodologies for the object-oriented modeling it is very difficult for beginners to understand and to model some systems. Unified modeling language (UML) is object orientated modeling tool based on use cases, architectures, iterations and increments.

UML (Rumbaugh *et al.*, 2004) is used as the standard tool for software development in early stages. UML is no a programming language but resided at a higher conceptual level than programming languages. Since it is standard tool for software development it was used in various applications for system modeling ranging from engineering modeling to business processes. The main purpose of the UML is system documentation and specification.

Various activities could be modelled by using UML diagrams. In this paper the waste cooking oil management software is analyzed and modelled with help of use case diagrams along with scenarios of activities and activity and state diagrams.

Literature Overview

The intention of study in Muralidharan and Vasudevan (2015) was to predict the performance, emission and combustion characteristics of a single-cylinder, four-stroke variable compression ratio engine fuelled with waste cooking oil methyl ester and its blends – standard diesel with the aid of artificial neural network (ANN) and this study was shown that there is a good correlation between the ANN-predicted values and the experimental data for different engine performance, emission parameters and combustion characteristics. Biodiesel from waste cooking oil (WCO) and soybean oil (SO) mixture was produced by changing the alkali catalyst (NaOH) content and the WCO to SO ratio in the feedstock (Primata *et al.*, 2013) and conclusion was implied that the waste cooking oil mixture, which contains 40 wt% fresh soybean oil, could be treated like the fresh soybean oil to produce biodiesel, and that this behaviour would be helpful to reduce the biodiesel production cost when waste cooking oil used as feedstock. There has been an alarming increase in the dumping municipal solid waste (MSW), predominantly food waste. One way of promoting an environmentally friendly method of minimizing food waste is to turn the waste into energy by producing biodiesel from waste cooking oils. Biodiesel is a biodegradable fuel that can be manufactured from food waste with a low price and sustainable supply. The purpose of research in Li and Yu (2015) was to produce biodiesel from waste cooking oils in the laboratory and compare the quantity and quality of products made from domestic waste cooking oil, restaurant cooking oil and fresh cooking oil. The feedstocks used were domestic deep-frying canola oil, domestic lard, deep-frying oil obtained from a restaurant and fresh canola oil. In a comparison of biodiesel yield and quality, household waste cooking oil was a better feedstock than restaurant waste cooking oil (Rumbaugh *et al.*, 2004). Waste cooking oils should be used for biodiesel production to turn waste into energy (Rumbaugh *et al.*, 2004). An acid–base-catalyst-based two-step biodiesel production experiment from soybean waste cooking oil was carried out to identify which parameter is the most influential among the experimental parameters by using the Taguchi method (Fajriutami *et al.*, 2013) and under the optimum conditions, waste

cooking oil was converted into crude biodiesel by a two-step process with fatty acid methyl ester content without any further post-purification. Physiochemical properties of biodiesel, a sustainable and green alternative fuel produced from renewable resources, are greatly influenced by the structural features of polyunsaturated, monounsaturated and saturated fatty acids. Two feedstock oils, potentially contribution to cleaner technologies, refined cooking oil and waste cooking oil derived from palm olein have been studied in article (Chuah *et al.*, 2017). Fatty acid compositions of the refined cooking oil and waste cooking oil were analyzed and confronted with other literature sources. With the proposed triangular chart for biodiesel properties prediction, potential biodiesel fuels from various feedstock oils can be analyzed (Chuah *et al.*, 2017). Growing demand for fuel in the industrialized and urbanized era coupled with the skyrocketing oil prices and growing concern over the adverse impacts on climate necessitate use of eco-friendly energy sources and recycling of wastes (Anitha, 2013). Article (Anitha, 2013) presented the results obtained from experiments on conversion of waste cooking oil into bio-diesel where the fuel properties of biodiesel obtained were found to be in agreement with standards. The use of metakaolinite as a catalyst in the transesterification reaction of waste cooking oil with methanol to obtain fatty acid methyl esters (biodiesel) was studied (Ramirez-Ortiz *et al.*, 2012) where results showed that metakaolinite is a prominent, inexpensive, reusable and thermally stable catalyst for the transesterification of waste cooking oil. Nano MgO is not capable of catalyzing the transesterification by itself, because it has a much weaker basic affinity but when used with Nano CaO due to its surface structure, the basic properties increase and it becomes a proper base for the catalyst so that CaO contact surface increases and transesterification reaction yield significantly increases as well (Tahvildari *et al.*, 2015). In study (Sodhi *et al.*, 2017), biodiesel was produced using waste cooking oil that was discarded as a waste in the environment. The properties of the feedstock were determined using standard methods. The transesterification process was implemented to extract the biodiesel, and this process was optimized and standardized by selecting three different parameters: molar ratio (methanol:oil), catalyst concentration (KOH) and reaction temperature. The study concluded that waste cooking oil has a great potential for waste to energy process (Sodhi *et al.*, 2017). The aim of the life cycle assessment study (Chua *et al.*, 2010) was to compare the environmental performances of biodiesel derived from WCO and low sulphur diesel in terms of global warming potential, life cycle energy efficiency (LCEE) and fossil energy ratio (FER) using the life cycle inventory where the results of this study would serve as a reference for energy policy makers and environmental agencies. The emission results and the life cycle energy efficiencies have indicated that the replacement of low sulphur diesel with biodiesel derived from WCO as a transportation fuel is favorable (Chua *et al.*, 2010). In study (Hosseini and Ju, 2015), the feasibility of pretreatment and/or upgrading of waste cooking oil (WCO) using the microalga *Ochromonas danica* was investigated where contacting the WCO with the phagotrophic *O. danica* cells was found to decrease the acid values of the remaining oil by 2.8 and 2.4 mg KOH/g WCO, respectively. The *O. danica*-pretreated WCO, with lower acid values, are potentially better feedstock for biodiesel production (Muralidharan and Vasudevan, 2015). The use of enzymes has several advantages, such as the absence of saponification side reactions, production of high-purity glycerol co-product, and low-cost downstream processing. In work (Vescovi *et al.*, 2016), biodiesel was produced from lipase-catalyzed hydrolysis of waste cooking oil (WCO) followed by esterification of the hydrolyzed WCO (HWCO) where it was found reuse hydrolysis and esterification assays showed that the immobilized enzymes could be recycled five times in 10-h batches, under the conditions described above. The results showed that WCO is a promising feedstock for use in the production of biodiesel (Vescovi *et al.*, 2016). A reactor has been developed to produce high quality fatty acid methyl esters (FAME) from waste cooking palm oil (WCO) (Buasri *et al.*, 2012) where continuous transesterification of free fatty acids (FFA) from acidified oil with methanol was carried out using a calcium oxide supported on activated carbon (CaO/AC) as a heterogeneous solid-base catalyst. The results showed that the FFA conversion increased with increases in alcohol/oil molar ratio, catalyst bed height and temperature, whereas decreased with flow rate and initial water content in feedstock increase. High quality waste cooking palm oil methyl ester was produced by combination of heterogeneous alkali transesterification and separation processes in a fixed bed reactor. In sum, activated carbon shows potential for transesterification of FFA (Buasri *et al.*, 2012). In the study (Farid *et al.*, 2017), a bioadsorbent produced from pressed-shredded oil palm empty fruit bunch was used to remove impurities from crude biodiesel derived from waste cooking oil. In comparison to commercial adsorbents and the water washing method, purification using the oil palm empty fruit bunch derived bioadsorbent resulted in higher removal of free fatty acids, potassium, water impurities and a smaller loss of fatty acid methyl esters. It was found that the use of the bioadsorbent improved the biodiesel quality besides its benefits of ease of operations and avoidance of waste water production (Farid *et al.*, 2017). The use of waste cooking oil and dimethyl carbonate (DMC) as a reactants was illustrated in article (Panadare and Rathod, 2017), enzyme as catalyst that facilitated the biodiesel production by providing low cost reactant, ecofriendly methodology and glycerol carbonate as marketable by-product. It is found that, about 94% conversion was obtained in just four hours using microwave irradiation when operated at optimized parameters which include temperature, enzyme loading, water content, molar ratio reactants and addition of surfactant. Lipase 435 used as a catalyst was found to recover 88% of its activity after catalyzing six successive reaction cycles. Biodiesel obtained was observed to fit ASTM D 6751 standards after least downstream steps (Panadare and Rathod, 2017). Improving the flow ability at a low temperature is vital for the utilization and popularization of biodiesel. The cold flow properties of waste cooking oil biodiesel-0# diesel blends with poly-alpha-olefin (PAO) pour point depressants were studied in Xue *et al.* (2016). Viscosity-temperature curves, polarized optical microscopy, low-temperature X-ray diffraction, and differential scanning calorimetry were used to explore the performance mechanism of PAO in biodiesel blends; and results presented that PAO could effectively lower the low-temperature viscosity, delay the aggregation of wax crystals and modify their crystallization behaviour by transforming the shape of crystals and depressing the formation of large wax crystals (Xue *et al.*, 2016). The International Maritime Organization (IMO) has enacted the Maritime Agreement Regarding Oil Pollution (MARPOL) VI to regulate the ship emissions. In the large ocean-going ship, the

marine auxiliary diesel engine is widely used to produce electricity, and it could also generate large amounts of harmful emissions (Geng *et al.*, 2017).

Methodologies for Software Development

Software development is very complicated and sensitive process. There are many subjects into the process with different tasks and goals. Since software could be very complex system there is demand to model different functions of the software separately to simplify the software development. Software could have dynamic and unstable nature since there are different technical and business aspect to model in the same time.

Early software developers did not use any specific methodology for software development for analyzing and modeling until for implementation and testing. In the meantime software developers were concluded that there are needs for software analyzing and modeling based on specific methodology. In other words it was established the concept of highly integrated software. It was lead to accept the methodology for general framework for software development. Accordingly the methodology could lead to better final result.

The models have to be created in order to understand the software behaviour and structure. Software modeling process shows the software visualization where one can see the software in graphical representation for easier observation.

RUP Methodology

Rational Unified Process (RUP) methodology has four main phases. The first phase is initial phase or idea inception where one needs to understand what should to do and software vision and requirements are identified. This phase includes the identification of key software actors (users) and use cases. Also there is need to identify software domain. Use case defines one sequence of an action which software performs that yields to an observable results. In the other hands one use cass presents result of an action by actor (Fig. 1). Use case presents the main part of some complete software operation from beginning until to the end. It is used to capture the intended behaviour of the system in development. By use cases models desired behaviour of the system could be specified but it is not strictly this desired behaviour to be carried out or implemented in the final product. Use cases models can be developed for whole system or for the part of system. Each part of system or subsystem can be developed by use cases models until the part produces some tangible amount of work and results. System complexity indicates the number of use cases. In the initial stage of system development main use cases are developed and additional use cases can be added or included when there is need for them.

The second phase is project elaboration where one needs to understand how to build the software and basic software architecture is showed in the phase. The third phase presents software construction where software testing is considered. The fourth phase presents software transition where software validation is performed. The RUP phases are shown in Fig. 2.

RUP models describes software in modeling. RUP models could be business models which describes business processes and business environment, use case models which describes what software doing and software environment, projecting models which describes use cases realization as code abstraction and implementation models which presents collection of components and subsystems.

Software development process could has different problems which needs to be identifies and solved before coding and testing. In order to solve problems there is need to find the problem causes. To remove the problem causes it is suitable to use best practices. For example in order to remove the confusion in communication between team members it is suitable to use standard language UML for the software visualization, specification and documentation. There are different types of UML diagrams which can be used in the software development process. There are two main classes of the ULM diagrams. These are structural and

Fig. 1 Use case model.

Fig. 2 RUP methodology phases.

behavioral diagrams. Structural diagram presents structure of the system in passive state and behavioral diagram present the active behaviour of the objects in a system or dynamical state.

Business Process Modeling

Business Process

Business process presents all operative procedures, rules, data and technologies of the companies. However mostly business processes are not optimized nor documented properly and therefore the processes are prone to errors and they are not understandable to all people. Business process enables goal fulfillment by transformation of inputs to outputs through producing some worth in the companies. The inputs and outputs could be information or products. People and machines transform the inputs to the outputs. The most known business process are operative process, support process and control process.

Business process are made as results of company project. Business process needs to be optimized in the mostly cases in order to improve the company efficiency. Also there is need to enable control and adaptation of the business process in order to track new trends and solutions. Fig. 3 shows the most important rules of the business process modeling. In the top there are standards which must be followed during the process modeling. The standards should answer to question what should one do. The second level is best practices where there are presented completed solutions of the some process. The second level answer to question how to work. In the other hand there is no need to develop solutions of product or process if there is already developed solutions of the product or process. The third level presents the software application in the some field of company in order to increase company efficiency. The last level represents the rules and procedures where it is described how software should implement in the particular organization.

Business process modeling should enable the specification of the all activities in the company in order to analyze, improve and automatize the processes. The models define users of the process, inputs and outputs, activities, etc. In order to model the business processes it is required to identify and describe the all processes which leads to the process complexity problem. To make easy understanding and analyzing of the business process it is required to perform software decomposition up to software components. Each of the software component is analyzed separately and the components interactions and relationship as well.

Object-Orientated Modeling of Business Process

UML is used for object-orientated modeling of business process. As already mentioned there are different UML diagrams for describing of software architecture and software behaviour. UML as standard language is used for modeling, for analyzing, for projecting and for implementation of the software system. Based on the object-orientated modeling all process could be presented by use cases models as rough specification and by structural diagrams and behavioral diagrams as detail specification.

During modeling of the business process it is not recommended to use natural language because of its ambiguity. Also, formal programming languages are not understandable for many people in the project team. Therefore it is suitable to organize the natural language to avoid ambiguity. Modeling process is one of the solutions for understanding and clear communication between project team members.

Rough software specification

Use case model could represent rough software specification, desirable software behaviour and activity sequence of the software which describes what software could do from the point of actors or users. The actor could be external user, internal user, another software or hardware. During modeling of use cases one can use standard specifications and relations like associations, generalizations, inclusions and extensions between actors and use cases and between two use cases as well.

Fig. 3 Rules of business process modeling.

Use case model should identify software users and what software should do. Also use case model should verify all requirements and to ensure communications with end users and experts. The main use case presents main functions of the software with main actors and software domain.

Detailed software specification

The next step after use case modeling is detailed software specification. This specification could be made by UML diagrams by software decomposition which shows use cases realization.

Each use case should be explained in detail. The first step is to describe normal and alternative activity flows in order to cover all predictable and unpredictable cases of the business process. One use case presents activity sequence. One sequence presents a scenario. There is normal scenario and an alternative scenario. The both of the scenarios should be written explicitly. Scenarios are instances of use cases. A scenario is systematic description of sequence of messages sent between actors and the system. Although there is large number of possible scenarios corresponding to a single use as it is important to write at least one non-trivial or normal scenario.

There is need to document each use case separately in order to specify use case. Activity flow and scenario should show what software should do but not how to do. Activity flow writing for particular use case needs to be done iteratively. In the other hand normal activity steps are written at first. Afterwards alternative activity step should be written as well in the next iteration.

There are different diagrams to explain use cases in detail like activity and state diagrams. Activity diagram is used for software modeling on different levels for business process, activity flows, procedure logic and etc. Activity diagrams is used for modeling software dynamical aspects based on activities.

State diagrams is used to describe behaviour of one object through several use cases. In the other hand state diagrams show life span of one object or several similar objects (class). State diagram is focused on object behaviour for particular activities. It describes how one object transform from one state to another by some activity. Each object should be in some state through its life span. This object state is changable through time or by some activity action. For example faculty teacher could change his state from assistant through assistant professor and docent until regular professor state. For each of the state there is need time and some activity to perform by object or candidate.

Waste Cooking Oil Management Software Modeling

Problem Description

The investigation is intended for the problem solving of collection and acquiring of waste cooking oil which is cancerogenic. The main objects of the suppliers which are implemented in the software of the waste cooking oil management are market objects, touristy industry, catering industry and industry objects. The main problems in collecting and acquiring of the waste cooking oil are:

1. Suppliers are not identified,
2. There is no technical support for the waste cooking oil management,
3. Insufficient usage of fuel in transport from renewable energy sources,
4. Insufficient education of the main suppliers of the waste cooking oil about the main problem of the waste cooking oil and suggestions for the problem solution.

The main goals of the investigation is to decrease the emissions of the greenhouse gasses and generally to decrease global warming. Also biofuels need to be introduced in the transport as much as it can. The main activities of the investigation should be:

1. To identify all waste cooking oil generators which are the most relevant,
2. To analyze the potential of the waste cooking oil generators,
3. To analyze quantity of the potential waste cooking oil,
4. To model software for waste cooking oil management.

Object-orientated modeling concepts are used during analyzing and modeling of the waste cooking oil management software. Two UML concepts are used for the software modeling like use case models, activity diagrams, state diagrams and scenarios of activities.

Waste Cooking Oil Management Software

Waste cooking oil management software should be use for organization of the waste cooking oil suppliers and collectors as well. The main advantage of the waste cooking oil management software in the article is in its universality and in its online usage. In the other hand it is possible to access to the software from any place and anytime.

The main feature of the waste cooking oil management software should be universal application for any subjects and any suppliers and collectors. The waste cooking oil management software will be framework of the suppliers and collectors of the waste cooking oil management activity. Also this software could be adapted based on new subjects or new material.

As users are considered, suppliers in different parts of the industry are collectors as well. All of the users should have username and password in order to access the waste cooking oil management database.

Collectors should made reports for different statistical analysis of the waste cooking oil. As the main problem of the current waste cooking oil management software it was identified limitation of unified approach for all subjects. Therefore it is required to develop information system which would allow to users to use the software anytime in order to enter desired data.

Waste cooking oil management software users

The waste cooking oil management software users could be divided based on natural basis according to working place, suppliers and collectors. All of the users have equal rights to access and use of the software. Therefore the main users of the software are:

- Suppliers (market objects, touristy industry, catering industry and industry objects),
- Collectors,
- Administrator.

Each of the users should have individual username and password in order to access to the software. Administrator of information system who needs to maintain the software and he is responsible for working of computer system and software as well. He gives permission to the staff's access to the waste cooking oil management database, maintains database, maintains web presentation of the waste cooking oil management and makes regular daily reports.

Waste Cooking Oil Management Software Analyzing

Each of the users should have individual username and password in order to access to the software. Administrator of information system who needs to maintain the software and he is responsible for working of computer system and software as well. He gives permission to the staff's access to the waste cooking oil management database, maintains database, maintains web presentation of the waste cooking oil management and makes regular daily reports.

Analyzing of the current state of waste cooking oil management software is crucial in order to get knowledge about advantageous and drawbacks of the current state and to find potential spaces to make the software better. The main goal of the article is analyzing and modeling of the waste cooking oil management software.

During analyzing process of the current waste cooking oil management software it is concluded that the suppliers and collectors of the waste cooking oil have the have universal software to improve the efficiency of the waste cooking oil acquiring. This software needs to have online and offline working regime since there is no need to be always online to track desired materials. The software should enable fast searching procedure for the material.

Main use cases diagram of the waste cooking oil management software

Waste cooking oil management processes are depicted by the main use case diagram as it shown in Fig. 4. The main use case diagram has several sub use cases which will be explained in detail. As can be see administrator should perform main administration process of the waste cooking oil management process in order to ensure smooth working processes by the software. Waste

Fig. 4 Main use case diagram of the waste cooking oil management software.

Fig. 5 Use case diagram – Software administration.

Table 1 Specification of use case: Giving permission for database access

Title	Giving permission for database access
Actors	Administrator
Trigger	It starts with the choosing of the option on user interface for the giving permission for database access
Pre-condition	PC is properly settled Administrator has needed knowledge for the tasks
Post-condition	Client received authorization for database access of waste cooking oil management software
Main scenario	1. Administrator receives the request for the giving permission for database access of waste cooking oil management software. 2. Administrator checks the request validity 3. Administrator fills the application form for the giving permission for database access of waste cooking oil management software 4. Administrator selects client category based on the quantity of the waste cooking oil 5. Administrator approves the request 6. Administrator prints the instruction for the application use 7. Administrator distributes the instruction to the client as the proof for the successful addition to the users of the waste cooking oil management software for the database access
Alternative	1. In the case if the request is incorrect filled based on the step 2 of the main scenario the administrator returns the request to the client with the instruction how to correct the errors in the request

Table 2 Specification of use case: Software maintaining

Title	Software maintaining
Actors	Administrator
Trigger	It starts with the choosing of the option on user interface for the waste cooking oil management software maintaining
Pre-condition	PC is properly settled Administrator has needed knowledge for the tasks
Post-condition	Backup of the waste cooking oil management software was made
Main scenario	1. Administrator checks if there is some large operation on the waste cooking oil management software 2. If there is some operation on the waste cooking oil management software, the administrator waits until the operation ends 3. If there is not operation on the waste cooking oil management software, the administrator prepares tools for the software maintaining 4. Administrator checks if the all functions of the waste cooking oil management software are proper 5. If some of the function of the waste cooking oil management software is not proper than the administrator starts the tool for correction of the function 6. Administrator starts the backup process of the waste cooking oil management software 7. Administrator records the time of the software backup
Alternative	None

Table 3 Specification of use case: Software web pages maintaining

Title	Software web pages maintaining
Actors	Administrator
Trigger	It starts with the choosing of the option on user interface for the web pages maintaining of waste cooking oil management software
Pre-condition	PC is properly settled Administrator has needed knowledge for the tasks
Post-condition	Backup of the web pages of waste cooking oil management software was made
Main scenario	1. Administrator checks if there is some large operation on the web pages of waste cooking oil management software 2. If there is some operation on the web pages of waste cooking oil management software, the administrator waits until the operation ends 3. If there is not operation on the web pages of waste cooking oil management software, the administrator prepares tools for the web pages of waste cooking oil management software maintaining 4. Administrator checks if the all functions of the web pages of waste cooking oil management software are proper 5. If some of the function of the web pages of education software is not proper than the administrator starts the tool for correction of the function 6. Administrator starts the backup process of the web pages of waste cooking oil management software 7. Administrator records the time of the web pages of waste cooking oil management software backup
Alternative	None

Table 4 Specification of use case: Software database maintaining

Title	Software database maintaining
Actors	Administrator
Trigger	It starts with the choosing of the option on user interface for the database maintaining of waste cooking oil management software
Pre-condition	PC is properly settled Administrator has needed knowledge for the tasks
Post-condition	Backup of the database of waste cooking oil management software was made
Main scenario	1. Administrator checks if there is some large operation on the database of waste cooking oil management software 2. If there is some operation on the database of waste cooking oil management software, the administrator waits until the operation ends 3. If there is not operation on the database of waste cooking oil management software, the administrator prepares tools for the database of waste cooking oil management software maintaining 4. Administrator checks if the all functions of the database of education software are proper 5. If some of the function of the database of waste cooking oil management software is not proper than the administrator starts the tool for correction of the function 6. Administrator starts the backup process of the database of waste cooking oil management software 7. Administrator records the time of the database of waste cooking oil management software backup
Alternative	None

Table 5 Specification of use case: Making of regular reports

Title	Making of regular reports
Actors	Administrator
Trigger	It starts with the choosing of the option on user interface for the making of regular reports
Pre-condition	PC is properly settled Administrator has needed knowledge for the tasks
Post-condition	The reposts were printed
Main scenario	1. Administrator checks if there is some large operation 2. If there is some operation, the administrator waits until the operation ends 3. If there is not operation, the administrator prepares tools for the making of regular reports 4. Administrator selects between standard procedure of the making of regular reports and nonstandard procedure where administrator can adjust the parameters of the reports. If nonstandard procedure was chosen than the administrator adjusts the parameters of the reports 5. Administrator starts the procedure of the making of regular reports 6. Administrator saves the backup of the reports 7. Administrator records the time of the database of making of regular reports
Alternative	None

Fig. 6 Use case diagram – Recording of quantity of waste cooking oil.

Table 6 Specification of use case: Recording of quantity of waste cooking oil

Title	Faculty or school selecting
Actors	Suppliers
Trigger	It starts with the choosing of the option on user interface for the recording of quantity of waste cooking oil
Pre-condition	PC is properly settled Waste cooking oil acquired
Post-condition	Recorded quantity of waste cooking oil
Main scenario	1. Client starts waste cooking oil management software 2. Client does login into waste cooking oil management education software 3. Client records the quantity of waste cooking oil 4. Client confirms the quantity
Alternative	1. The recording of quantity of waste cooking oil is canceled 2. Due to technical problems the service cannot be made

cooking oil management clients or suppliers could record the quantity of the waste cooking oil if they are logged in the software database. Collectors will perform reconditioning of the waste cooking oil only after clients or suppliers confirmed the recorded quantity of the waste cooking oil.

Use cases of the waste cooking oil management software subsystems

Software administration

Based on the analyzing of cooking oil management process it is noted there is need for new computer system for the sector. Accordingly there is need for person who will maintain administration of the software and the computer system. Therefore there is need for a software administrator.

Fig. 7 Activity diagram – Recording of quantity of waste cooking oil.

Fig. 8 State diagram – Recording of quantity of waste cooking oil.

Administrator performs software administration in order to eliminate all unpredictable errors in the software and system. Administrator has full responsibility for the software maintenance. They will give permissions for other users access to the system, maintains the software, maintains the web pages of the software, maintains the software database, and makes regular daily reports. Fig. 5 shows the use case diagram of the software administration. As can be seen there are five functions of the administration which will be explained in details by scenarios.

Table 1 shows detailed specification of use case for giving permission for database access of the waste cooking oil management software by administrator.

Fig. 9 Use case: Reconditioning of waste cooking oil.

Table 7 Specification of use case: Reconditioning of waste cooking oil

Title	Reconditioning of waste cooking oil
Actors	Collector
Trigger	It starts with the choosing of the option on user interface for the reconditioning of waste cooking oil
Pre-condition	PC is properly settled Recorded quantity of waste cooking oil
Post-condition	Produced biodiesel
Main scenario	1. Collector receives quantity of waste cooking oil 2. Collector performs transesterification process of the waste cooking oil
Alternative	1. The reconditioning of waste cooking oil is canceled 2. Due to technical problems the service cannot be made

Table 2 shows detailed specification of the use case of waste cooking oil management software maintaining by administrator.

Table 3 shows detailed specification of use case for web pages maintaining of waste cooking oil management software by administrator.

Table 4 shows detailed specification of use case for database maintaining of waste cooking oil management software by administrator.

Table 5 shows detailed specification of use case for making of regular reports by administrator.

Recording of quantity waste cooking oil

Use case diagram for recording of quantity waste cooking oil in the software is shown in **Fig. 6**. As can be seen the use case has several activities in order to record the quantity waste cooking oil. These activities are database accessing, new form opening, new data entering, data saving and data confirming. Login into the software is necessary action before perform other main activities. As can be seen suppliers (market objects, touristy industry, catering industry and industry objects) and are the main users of the use case.

Table 6 shows detailed specification for use case recording of quantity of waste cooking oil. **Fig. 7** shows activity diagram for recording of quantity of waste cooking oil. **Fig. 8** shows state diagram for recording of quantity of waste cooking oil.

Reconditioning of waste cooking oil

Use case for reconditioning of waste cooking oil by the software will be explained by sub activities in the use case as can be seen in **Fig. 9**. As can be seen the use case is composed of two activities. The main activity is biodiesel production from the waste cooking oil. In order to perform the main activity one sub activity needs to be established. The sub activity is performing transesterification process of the waste cooking oil. As users of the use case there are collectors.

Table 7 shows detail specification of use case for reconditioning of waste cooking oil.

Conclusion

An attempt for modeling of universal waste cooking oil management software was expressed in this paper by applying object-orientated modeling approach by using unified modeling language (UML) which is standard language for software visualization and modeling. The main concepts of the object-orientated modeling was described in the article. Generally, the waste cooking oil management software development was done by UML approach. Use case diagram and UML diagram was used for the waste cooking oil management software development and modeling. Afterward the main and alternate scenarios were written for each set of activity.

Since the UML has become a standard modeling language accepted widely by the industry leaders and a tool of communication between system users, analysts and programmers it is beneficial to develop models by using the UML. The UML developed models could be implements in any object-orientated language to become platform independent.

Visual modeling is a way of thinking about the problems from reality. The models are used for problems understanding, for communications between team members which are included in the project, for modeling of company, for documentation

preparation and for program and database design. Modeling enable better understanding of requirements, clean design and better support and maiming of the systems.

UML has become standard language for software modeling. ULM enables full tracking of project development process through fill life cycle. Because of the analysis through UML programming time is significantly reduced since mostly problems are identified in initial stage by modeling in UML. Programmers get full documentation and specification and new team members could be easily added in the project.

We develop all use cases of the waste cooking oil management software in the article. Also all scenarios are written for the all activities. The way of modeling could enable easy further development for the software.

Introduction

The life on earth today is combating the worst effects of environmental degradation brought about by human exploitation. Environmental degradation has directly reduced the quality of life on earth and also resulted in producing extreme scarcity of resources. Polymers which were once believed a boon to mankind, over the years have turned out to be environment's primary bane. To counter this condition, there is an immediate need to make these polymers environment-friendly. Governments around the world are imposing strict norms and are calling for stringent adaptation of 3Rs: Reduce, Reuse and Recycle. Industries are now searching for alternatives to comply with regulations and come up with products that are more 'green'. Thus, polymer composites are fabricated by incorporating organic, biodegradable natural fiber reinforcements instead of the most widely used synthetic fibers such as glass, aramid and carbon fibers. Bio/Natural fibers are derived from plants, animals and other geological processes. Natural fibers are made up of clusters of microscopic cells and possess a negligible diameter in comparison to their length. Polymer matrix composites reinforced with nature-derived fibers exhibit excellent strength-to-weight ratio, superior mechanical properties such as elastic modulus, flexural strength, and shear strength (Tajvidi *et al.*, 2006). Due to these inherent properties, the natural fiber reinforced composites find a wide-spread application. The use of locally available natural fibers also help to bring down the cost of the composites by a greater extent, alternatively helping the agriculture sector to find a means for sustainable income.

Classification

Bio fibers are classified based on the source from which they are derived from such as plant, animal and mineral derivatives. Fig. 1 illustrates the classification of bio fibers.

Application

The most primitive application area of bio-fibers is textile (Robinson, 1969). Since ages man has clothed himself in the cloth weaved from threads spun from various bio-fibers such as cotton, silk and wool. To make the fabric look attractive the bio-fibers of cotton, wool and silk are dyed in an array of colors. Both natural and synthetic dyes are used to beautify the fabric (Cristea and Vilarem, 2006). But technological advancements have led to the use of many bio fibers in various industrial applications. The following sections highlight the use of some of the most abundantly available bio fibers throughout the world.

Banana Fibers

Banana which is rich in nutrition is the world's fourth most important food (Reddy and Yang, 2015). Fibers derived from the stem of the banana plant has grabbed the attention of several researchers due to its attractive tensile strength (458 MPa) and tensile modulus (17 GPa) (Pappu *et al.*, 2015). Banana fibers are derived through mechanical means from the stem of the banana plant. The long fibers thus extracted are subjected to enzymatic treatment under optimized conditions to produce yarns (Ortega *et al.*, 2016). The treated banana fibers are used as reinforcement for polymeric composites. The treatment of banana fibers is needed to reduce the hygroscopicity by eliminating lignin, pectin, waxes and other such water soluble substances. Fiber treatment also improves the wetting of the fiber with the polymer matrix resulting in a composite with superior properties such as tensile, impact and flexural strength (Venkateshwaran and Elayaperumal, 2010). Banana fibers are used not only in cottage industry to produce

Fig. 1 Classification of bio-fibers.

ropes, floor mats, carpets and bags, but are also used extensively in paper and textile industries across the globe (Ray *et al.*, 2012). Banana fiber yarn can be spun to a scale as small as 10 nano-meter making it the most sought after material to produce summer wears, textured apparels, socks, cushion covers, rugs, neckties, curtains and table cloth. Banana fibers

Jute Fibers

Jute is known as the 'golden fiber' due to its silky texture and golden sheen. It is majorly extracted from the hard bark of *Corchorus capsularis* plant grown mainly in south Asian countries. India is the largest producer of jute in the world. Jute is harvested annually and the crop takes approximately four months to grow with almost nil application of fertilizers and/or pesticides making it the most affordable. It is one of the most widely used natural fiber with application areas spanning from textiles to automotive fields. Sacks woven from jute fibers were extensively used during the period of industrial revolution in 18th century. Till date, jute fibers are primarily used for sacking simple agricultural produce to rigid packing. Jute fibers are woven to produce strong ropes owing to their superior strength. Various cottage industries thrive by producing textiles woven from jute which are used to produce curtains, carpets, cushion coverings and rugs. Jute, when treated through the application of caustic soda, is rendered soft and pliable making it easy to blend with wool. Blended fibers are then used to produce clothing and furnishings that have huge market worldwide. Jute is one such natural fiber which imparts excellent tensile strength to epoxy composites and can be used directly without any prior treatment as the strength imparted to the composites through untreated jute fiber does not show significant variation with the incorporation of treated jute fiber (Rashed *et al.*, 2006). This brings down the cost of composite fabrication by a greater level. The improve in various mechanical properties of jute reinforced polymer composites is due to the fact that jute contains very high proportion of cellulose which renders excellent stiffness to the fibers. Studies have indicated that jute fibers can effectively replace glass fibers as composite reinforcements in the production of automobile component such as bonnet (Alves *et al.*, 2010). Jute fiber reinforced concrete is found to exhibit superior flexural, compressive and tensile strength over unreinforced concrete, thus increasing the scope for inclusion of jute fibers for structural applications (Zakaria *et al.*, 2017). This scenario would enable the surge of low cost, sustainable housing solutions worldwide.

Coconut Fibers

'Coir' is the tradename given for coconut fiber which is derived from the inner husk of coconuts. Cellulosic fibers bonded together with lignin and hemicellulose constitute coir. The proportion of lignin in the coir is very high as compared with the proportion of cellulose. This renders coir with a low tensile modulus and strength. Coir also possesses very high elongation at break which renders coir most suitable for cushioning applications such as seating for automotive (Nam *et al.*, 2011). The high lignin content makes coir more moisture resistance thus reducing the adverse effect of fungus and bacterial decay (Khedari *et al.*, 2004). Traditionally, coir is used to produce mats, ropes, blinds, mattresses and decorative items. Coconut producing countries like India have setup coir boards exclusively to develop and promote value addition to coir. In India coir pith is a waste that is generated from numerous coir processing industries. This large amount of waste in the form of coir pith is used to produce activated carbon through chemical treatment economically (Namasivayam and Kadirvelu, 1997). It is also used to adsorb dyes from aqueous solution resulting from textile industries. Coconut fiber mats are employed as an underlayment for floor covering for indoor sports arena owing to their superior elasticity, resistance to wear and moisture (Schomerus, 1981). Densified coir dust briquette has excellent calorific value of around 4000 kcal/kg and can be effectively used as energy source (Hamidul Islam *et al.*, 2014). Coir finds its extensive use in the field of agriculture due to its inherent characteristics such as high water retention, resistance to fungus and bacterial attack. Due to its extremely high lignin content (approx. 40%), coir decomposes very slowly and hence does not rot quickly. 'Coir dust' which is traded in the name of 'Coco peat', a byproduct of short coir fiber production, is considered a boon to the farming community. It has been proven that through the addition of as less as two percent of cocopeat to loamy soil, the moisture-retention of the soil increased to 40% from 24.3% (Hume, 1949). Coconut fiber reinforced polymer composites have gained the attention of researchers and industries throughout the globe as coconut fibers possess a natural wax layer that aids in the promotion of a strong interfacial bonding between the polymer resin and the fiber (Brahmakumar *et al.*, 2005). Coir reinforced polymer composites indicate good flame retardancy and such composites qualify as good materials for automobile interior applications (Ayrlimis *et al.*, 2011).

Bamboo Fibers

Bamboo is an evergreen plant belonging to Poaceae grass family. Bamboo possesses superior compressive strength which is greater than that possessed by concrete, brick or wood. It has a tensile strength value which is almost exceeding the steel's tensile strength (Amatosa Jr. and Loretero, 2017). Bamboo is a tropical plant which thrives in the hot and humid regions of the world. Bamboo is the fastest growing evergreen plant with growth rate ranging from 300 to 1000 mm per day and is known to reach maturity in as little as five years. The traditional applications of bamboo include structural constructions, furniture, weapons, tools, utensils, textiles and musical instruments due to their extremely high strength to weight ratio. The fibers extracted from bamboo are almost equivalent to glass fibers in their strength and modulus (Osorio *et al.*, 2011). This is mainly due to the fact that bamboo fibers are composed of cellulose (60%) coupled with higher concentration of lignin and a small micro-fibril angle. Cross-ply poly-lactic acid

laminates reinforced by bamboo fiber can suitably replace glass fiber based composites used as skins for sandwich structures. Carbonized bamboo fibers molded into sheets have been successfully employed as a gas diffusion layer of proton exchange membrane fuel cells which is a greener and sustainable step towards reducing the usage of carbon fibers (Kinumoto *et al.*, 2015). Woven bamboo fiber reinforced composites possess excellent mechanical properties and are found to be a good substitute for cotton and nylon fiber based composites in orthotic and prosthetic devices (Kramer *et al.*, 2015). Epoxy composite reinforced with bamboo fiber performs better than conventional aramid fabric plies in multilayered ballistic armors with nearly 22% superior ballistic performance, ensuring both safety and cost effectiveness (Cruz *et al.*, 2015). Bamboo fiber reinforced nano-hydroxyapatite/poly (lactic-co-glycolic) composite scaffold exhibit the required porosity and porous structure coupled with compressive strengths that are extremely superior to the conventional n-HA/PLGA composite scaffold indicating that bamboo fiber reinforced composites are the candidate materials for bone tissue engineering scaffold (Jiang *et al.*, 2017). Bamboo fibers are a rich source of dietary fibers possessing good hygroscopic properties, excellent stability to emulsification and compatibility of color for meat based products. Hence, bamboo fibers can be applied in the formulation of chicken burger acting as a substitute for animal fats (Huber *et al.*, 2016). Bamboo fibers have been successfully incorporated in 'Amaretti cookie', an Italian food. Bamboo fiber incorporation resulted in an enhanced textured, flavorful and tastier cookie (Farris and Piergiovanni, 2008). The use of bamboo fiber based biofilm carrier for bio-contact oxidation reactor employed for waste-water treatment is proven to be far superior in effluent removal under fluctuating loads as compared to the prevalent activated sludge system (Xiao and Chu, 2015). Bamboo fiber are candidate materials for providing low-cost, sustainable buildings and houses. Bamboo fiber reinforced concrete beams have performed well under cracking as the bamboo fibers tend to reduce the width of the crack and arrest beam deflection, thereby enhancing the beam's load-carrying ability post cracking (Dewi and Wijaya, 2017). Bamboo fibers have been employed in the production of Wood-free material for paperboard packaging (Shi *et al.*, 2018). Bamboo fiber reinforced composites possess good fire retardant characteristics enabling their application in the field of automotive. Technological enhancements in injection molding process has enabled the incorporation of bamboo fiber based polymeric structures for automobiles (Partanen and Carus, 2016). The excellent strength and wear resistance possessed by bamboo fibers have led to their incorporation in semi-metallic matrices to produce composites for brake friction materials employed in automotive applications (Talib *et al.*, 2016). Bamboo fibers are mixed with polylactic acid resin along with a natural binder to produce a speaker diaphragm which can produce high quality rich sound with enhanced audio experience for electronic devices (Jin *et al.*, 2015).

Flax Fibers

Flax, also called as linseed plant belonging to Linaceae family, is a very versatile food plant cultivated originally for its fibers and recently for its oilseeds which are known to be a rich source of ω -3 and α -linolenic fatty acids that are essential to prevent cardiovascular diseases. Fibers from the stem of the flax plant are derived through the process called 'retting'. The flax fibers are extensively used for the production of linen garments and is one of the oldest known luxury fiber (Farrer and Watt, 2015). Long length flax fibers are used to produce superior quality linen garments such as bed spreads, inner wears, table cloth, bathrobes, hand towels, lace, socks and stocking, while the short flax fiber is utilized for the production of ropes and twines. Flax fibers are extensively used for the production of superior grade paper employed for printing currencies, production of tea bags and cigarette rolls. Apart from its traditional use in textile industry, flax fibers, off late are being incorporated as reinforcements for production of variety of composite materials having innumerable applications. This in turn possess challenges for flax cultivators and breeders to produce flax fibers with specific characteristics in large quantities. Flax fibers have excellent specific tensile modulus (20×10^3 to 50×10^3 mm²/s²) coupled with extremely good tensile strength of 1500 N/mm² for single fiber to 800 N/mm² for fiber bundle (Sojoudiasli, 2017). Due to such superior properties, flax fibers are considered to be the best replacement for glass fibers. Long, unidirectional, nonwoven flax fiber reinforced composite panels employed for load bearing floor panels in a passenger vehicle compartment resulted in a drastic reduction in the total weight of the vehicle coupled with extreme durability under the applied load (Akampumuza *et al.*, 2017). Automobile giant such as Mercedes have incorporated flax fiber reinforced polyester composite for encapsulating their bus engines which resulted in a 5% reduction in the total weight of the buses, thereby improving the fuel economy (Koronis *et al.*, 2013). This prompted the manufacturers to incorporate flax fiber reinforced composites in shelving for parcels and coverings for the rear trunk in the 2006 Mercedes Benz S-class luxury car (Wallenberger, 2001). Another auto-giant, Audi, in its 2000 model of A2 car utilized the flax/sisal fiber reinforced polyurethane door trim composite panels. Flax fiber reinforced polymer sandwich panel exhibited superior impact resistance and thus are successfully used for building cladding and roof slabs (Betts *et al.*, 2018). Light weight, ventilated facades for buildings made out of nonwoven flax fiber reinforced Portland cement are considered to be apt replacement for the current heavy building materials such as ceramics and stones due to their superior strength to weight ratio, high durability, ductility, insulating capacity and ease of incorporation of required aesthetic features (Claramunt *et al.*, 2016). Flax fiber composites are extremely resistant to the formation of molds and fungal attacks (Segovia *et al.*, 2016) making them candidate building construction materials. Flax fibers are very good insulators and are ideally used to provide thermal insulation for the buildings. Flax fiber composites find their use in the field of medicine. Flax fiber reinforced Polycaprolactone composites are beneficial for accelerated bone regeneration (Gredes *et al.*, 2016). Efforts have been made to come up with disposable wet wipes for removable dental appliances incorporating nonwoven cellulosic fiber such as flax fiber (Tricca *et al.*, 2018). Modified flax fibers with induced polyhydroxybutyrate gene are considered to be

exceptional biomedical materials that promote proliferation of human fibroblast coupled with high antimicrobial properties and such fibers are successfully utilized for the production of wound-dressing gauze (Kulma *et al.*, 2015). Knitted flax fiber mesh is a new class of implantable structures in surgical procedures such as for the repair of the incisions of the abdominal wall due to hernia (Michel *et al.*, 2014).

Introduction

Soil is a valued commodity for use in household construction in rural Rajasthan, India (Niroumand *et al.*, 2013). Soil and carbonaceous material blends have been used in the manufacture of ceramics for water storage and cooking (Roux, 2015). The skills to cast clayey soils and spin wheel are vital in cruse manufacturing. These cruse are manufactured from local soil, small pebbles and organic material such as wood waste, donkey dung etc. (Roux, 2015). Cruse manufacturing can be traced back to the Mesolithic period in this region. The importance to pottery, settlements and domestication of animals towards the west of the Vindhya in India were observed during this period (Agrawal, 2007). Arid areas of the Thar lie to the West of the Vindhya Ranges in India.

Western Rajasthan is arid and has desert loam soils. Soil should have adequate fertility in order to be utilized for production of crops. Generally dung or ordure is added to enhance soil fertility (Chandra, 2005). Compost of plant materials is also added to attain similar fertility enhancements (Haug, 1980). It is advantageous, if the soil and carbonaceous mixtures are pressed together, organically protected and into arid soils (Satankar *et al.*, 2017). This hybrid composite plays an important role in soil quality revival and waste management. Apart from ecological advantage, such hybrid composites enhance the value of animal waste (Thakur *et al.*, 2013).

Ceramics from mud and organic materials are also used to produce functional ceramics which help water filtration (Plappally and Lienhard, 2013). Similar ceramic devices namely the G filter is also molded and baked by local hereditary potter families of this region. Further they also manufacture the cruse for water storage.

This article discusses the soil based blends or immingles specific to western Rajasthan, India. It is important to know the geographic location where these materials are used. For clarity, the geographical position in focus is bounded on the east and west between latitudes 26°48' 56.42"N and 27° 25' 15.18"N and longitudes 69°33' 18.95"E and 74°42'2.02"E. Further latitudes 28°31' 38.65 N and 23° 40'11.013"N and longitudes 72° 17'36.98" E and 73°33' 13.91"E respectively bound the region in the north and south.

It is said that accumulation of sea water occurred in this area during the post tertiary era (CGWB, 2008). Recent report confirms that Pachpadra town in this area was one of the three major salt lakes in Western Rajasthan (CGWB, 2008). Specific conductance of soil here ranges between 385 to 46,580 micro mhos/cm. at 25°C (CGWB, 2008). Luni river which disappears into the Rann of Kutch in Gujarat, India flows through the Thar Desert in Rajasthan. Luni (in local Marwari dialect) means salt and thus reverberates presence of salt in the region.

Soil-Carbonaceous Matter Immingle (SCMI)

The soils with clayey nature are appended with carbonaceous matter for utility in different traditional products, devices, practices, and processes. Most of the compositions are heterogeneous. In Rajasthan, the soil-carbonaceous matter immingle (SCMI) finds its use in household construction, soil and water use management. A similitude in the compositional ratio of composites and ceramics thus manufactured from these immingles are shown in Fig. 1.

SCMI for Surface Finish

Traditionally, soil-cow dung paste is applied on walls, floors, kilns, and earthen stoves as a finishing coat or cleansing coat across households in India. This coat is considered as a benchmark of daily cleaning activity of rural households in India. The wall finishing process shown in Fig. 2 is a low cost operation usually performed by local women. They incorporate aesthetic design using red mud and charcoal.

Cow dung is used for the finishing purpose due to its fine texture. Small size of plant based particulates suspended within cow dung is responsible for its fine texture and hence suitability for finishing application. Particulates within horse dung are comparatively large compared to cow dung. Size of particulates plays an important role in animal dung use (Satankar *et al.*, 2018).

Fresh cow dung and red soil taken in ratios of 1:2 by volume is uniformly mixed for producing the finishing paste. Further water equal to the volume of cow dung is added to provide coat consistency adhering to the spatula test. The paste is manually applied on the dry surface of the wall as per aesthetic requirements of the household.

While performing wall finish, paste is applied from bottom to top. The patches and cracks on the walls are also repaired using this paste. Finally a tint of water is also applied to obtain a smooth finish.

Fig. 1 SCMI based products and processes.

Fig. 2 Local women folk performing periodic finishing on mud structure.

The wall depicted in [Fig. 3\(a\)](#) is manually finished by hand. The saturated red coarse-cow dung soil immingle is impressed with a design shown in [Fig. 3\(b\)](#). The design is made by smallest fingers of both hands joined together at their tips. This in turn results in the formation of the crests and troughs. Once plaster saturates, the water flows down the crests and passes along the troughs to reach the bottom without harming the underlying immingle plastered on to the stone walls. This patterning prevents wear due to precipitation.

SCMI for Rural Household Construction

Composites manufactured from horse dung (*Equus* family) and local clayey soil is used to manufacture low load bearing structures (such as shelves as shown in [Fig. 4](#)) within households. Here the composites contain equal quantities of horse dung and soil. This technology is inherited by local “Santhi” tribal women of this region under study. The technology is limited and performed within the areal expanse of Marwar within which Marwari breed horses sustain ([ICAR-NRCE, 2017](#)).

The existence of this local *Equus* breed provides an insight that people from ages were aware of the properties of Marwari equine ordure. The Santhi community people believe that ordure have medicinal properties which prevent respiratory, microbial and other contagious diseases. The similar mixture also finds its application in manufacturing grain storage containers. *Equus* dung thus finds its application in manufacture of load bearing structures and flexural members.

The horse dung composites also have clayey soil in them. These soils are excavated from local ponds. These water harvesting structures deposit materials due to chemical weathering of rocks. The soil is thus characterized by high content of MgO , SiO_2 and Na_2O ([Satankar et al., 2017](#)).

Found in large chunks, the pond soil is soaked in water for a day. The aged slurry of pond soil and horse dung is mixed uniformly to make the wet mass. An equal volume of pond soil and horse dung is considered the correct ratio for manufacturing

Fig. 3 (a) Rural stone wall building finished with red soil and cow dung immingle (b) The crest and trough impressions.

Fig. 4 Aesthetic household shelf of soil-horse dung composite.

aesthetic shelves. This wet mass is spread on a bamboo cantilever structure protruding from the stone walls and pressed manually. The structure shown is then allowed to cure for sufficient time before use.

SCMI for Fertilization

About 40% of the arid areas of India (49.5 mha) is composed of Thar Desert in Rajasthan (Narayan and Kar, 2006). Sandy soils, negligible precipitation, and mining resulted in erosion, salinity of soils and degradation of vegetation cover. Dumping of stone, mine and industrial wastes also contribute to desertification in this region (Kaurwar *et al.*, 2018). SCMI composites with any animal dung can be used for fertilization (Dave *et al.*, 2017).

SCMI for Making the Cruse

Earthen cruse is used across the world for storing and cooling water especially during summer. These may vary in size, shape and color with geographical variability. The baked ceramic off-white pots are manufactured by local potters of Thar desert region using different material composition and firing techniques.

Potters in this region used donkey dung as a pore forming material in manufacturing of cruse (which is uncommon from other parts of world). The use of animal dung as pore former has now been replaced by sawdust due to decline in population of donkeys (*Equus* family) in this region (Satankar *et al.*, 2018). The cruse manufactured with soil-donkey dung immingle is

found to be comparatively weightless and compressively stronger than the cruse manufactured using soil-sawdust immingle (Satankar *et al.*, 2018).

Traditionally three ingredients salty clay, sawdust and granite gravels are used as base materials for cruse manufacturing. The clay can be procured from Pachpadra and Pokhran, Rajasthan. The working immingle must contain 45 liter equivalent of clayey soil. Water equal to one-third the volume of soil is used to produce wet mix. The other constituents are 9 liter equivalent of wood waste (collected from nearby timber businesses) and 2 kg of Saltpetre respectively. The women potters' helps in preparation of raw material and mixture while men potters cast the cruse on wheel.

SCMI for Making the Water Filter

The potters in Western Rajasthan are acquainted with rotating wheel based pottery. The clay ceramic water filter receptacle is shaped with a frustum shaped mold. Salty clay is mined from Raital and Mokalsar near Jodhpur, Rajasthan. The women folk (irrespective of the location of potter across India) powder and sieve the clay using a household sieve (3 mm $\times$ 3 mm).

Traditionally potter interprets the salinity of clay by tasting. If the desired salinity is missing rock salt equivalent to 0.02% by volume of soil is added to it. Addition of salt is considered to make the clay ceramics more load bearing, and functionally better in cooling characteristics. Local artisans believe that addition of salt in clay influence the sintering rates of clay ceramics. Sieving of sawdust is performed with the same sieve used for the powdered clay. This is analogous to the Potter for Peace method of preparing the clay-sawdust mixture for manufacturing of the frustum shaped ceramic water filter (Gupta *et al.*, 2018).

Composite for Rural Construction and Fertilizers

Composite Preparation Analysis

It is important to retrodict the technical reason behind sustainable use of equal volumes of soil and horse dung for constructing aesthetic shelves. Therefore clayey soil (C) and horse dung (H) in volume fractions of 30:70, 40:60, 50:50 and 60:40 respectively were mixed, shaped and analyzed. The analysis elaborates study of curing, flexural strength and fracture toughness property of C-H composites.

Equal volumes of the horse dung (H) & pond soil (C) were manually powdered and sieved (Satankar *et al.*, 2017). Local pond soil was soaked in sufficient quantity of water for 24 hours and then next day stabilized with powdered horse dung (Satankar *et al.*, 2017). The resulting dough was then formed into a rectangular shape (of size 250 mm $\times$ 50 mm $\times$ 20 mm). The resulting shapes were exposed to open environment (temperature of 35°C, humidity of 42%) for about 28 days. The change in weather parameters, composite weight and its dimension were noted during this 28 day curing period (Satankar *et al.*, 2017). The raw material volume, the immediate environment, and time play an important role in defining the weight of the cured sample (Satankar *et al.*, 2018).

The scanning electron image analysis of horse dung shown in Fig. 5 indicates calcium richness. The white flakes adhering onto the base are nanoparticles of calcium carbonate (Satankar *et al.*, 2017). Nanoparticles of CaCO_3 adhered to cellulose content provides horse dung composites with characteristics of a bio cement (Satankar *et al.*, 2017). An increase in horse dung would prevent C-H composite failures due to bending. The presence of calcium carbonate will also influence surface finish

Fig. 5 Scanning electron imagery of soil-horse dung C-H composites.

Fig. 6 Curing of composite samples.

Fig. 7 Flexural strength as a function of volume of horse dung in the C-H composite.

and thus surface energy of C-H composite (Satankar *et al.*, 2017). The low surface energy help in production of structurally strong manure cakes which disintegrate slowly in soil. A novel way of manufacturing slowly disintegrating fertilizer materials is thus envisaged.

Composite Curing Studies

Weight loss gradient was large during first week for all C-H composite samples. The weight loss varied from 25% to 39% in the different C-H composites tested. Curing rate hence is considered to peak during the first week while it petered after the second week. The samples containing more volume fraction of horse dung comparatively weighed less. Fig. 6 below indicates weight loss of C-H composites during curing. Density of the 28 day cured sample varies from 1120 to 1980 kg/m³ (Satankar *et al.*, 2018). Stability in weight of C5H5 is observed after the second week of curing.

Mechanical Strength of C-H Composite

C-H composite structure built with C5H5 composition is a flexural member. From Fig. 7 it is evident that flexural strength of C5H5 is better than any other composition of C-H composites. Flexural strength follows a quotient response based multiplicative distribution as a function of curing age (Satankar *et al.*, 2018). M5H5 samples were found to have visually uniform surface compared to all other compositions (Satankar *et al.*, 2018).

Fig. 8 Fracture toughness of C-H with varying volume fractions of horse dung.

Fig. 9 Geotextiles of *Leptadenia Pyrotechnica* (left) and *Crotalaria Burhia* (right) embedded with C-H Composite.

The property of fracture toughness in C-H composites follow a cyclic pattern as illustrated in **Fig. 8**. Fracture toughness values of the traditional C-H composites follows a generalized three parameter pareto model (Satankar *et al.*, 2018).

The packaging of such composites within geotextile mats is used in managing soil quality and productivity (Dave *et al.*, 2017). The packaged hybrid composite is shown in **Fig. 9**. The hybrid composites are embedded in the arid sandy loam soil in wet saturated condition as shown in **Fig. 9** to trap moisture for a long time beneath the soil surface.

SCMI Ceramics for Water Storage

Cruse manufactured in western Rajasthan is off-white in color (Roux, 2015; Kaurwar *et al.*, 2017a,b). The process of cruse manufacturing has not varied across India since ages (Satankar *et al.*, 2018). The off-white color is due to high content of MgO and CaO oxides on the cruse outer surface (Kaurwar *et al.*, 2017a,b). The non oxidative and oxidative sintering on the inside and outside of the cruse is evident with the color differentiation between the two surfaces. The internal wall of the cruse is red in color. This distinctiveness is supported by comparatively high percentage of Ca and Fe on the internal wall of the cruse.

The selection of clay is very important and depends on potters experience in cruse manufacturing. The excavated clay is collected at a specified location where it is exposed to the open atmosphere. The degeneration process that occurs during this period makes the soil better to work. A clay ball is shaped manually by placing it at the center of the spinning wheel.

Further the shaped vessel is preheated under sunlight during winter and in shade during summer. Preheating process provides optimum hardness and plasticity for further processing. Then hand building of the shaped vessel is performed. This provides the

Fig. 10 (a) Thrown cruse (b) Paddled cruse.

required shape and size for the cruse as shown in **Fig. 10(b)** (Kramer, 1997). The product dried in open for a week is then fired using up draught kiln to around 550–750°C (Kaurwar *et al.*, 2017a,b).

Baking

The manufacturing of pots is a seasonal process and is not carried out during rains and summers (Vincentelli, 2000). Baking has been performed using two firing techniques open firing and firing in a kiln (Ravi *et al.*, 2007). Out of these two techniques open firing is oldest and still popular among potters of different parts of India (Ravi *et al.*, 2007). The kiln preparation and loading requires 2–3 h while firing time depends on the type of the method used. The firing is usually done at night. The sintered products are allowed to cool in the furnace till next morning (Roux, 2015).

Baking preference is a procedural choice rather than thought of design for the potter (Guo, 2017; Roux, 2015). These procedural choices correspond to the culture, climate, traditional knowledge inertia, and social narratives related to local deities (Guo, 2017; Roux, 2015). The technological changes are more resistant to adoption in domestic manufacturing than decorative styles (Habicht-Mauche *et al.*, 2006).

The open firing process is usually performed on flat surface where the raw products are arranged in circular pattern over a bed of dried chopped grass or materials from agriculture residue. Agriculture waste, animal dung, twigs and leaves are used as a fuel (Roux, 2015).

Open firing provides temperatures of 500–850°C (Vincentelli, 2000). This technique does not leave waste and hence less technological evidence of its practice (Vincentelli, 2000). The open firing process does not need infrastructure but requires great technical expertise and observational skills to obtain required results (Perryman, 2008). Potters practice transfer of this technology within their household (Perryman, 2008). By 1970s, potters of this region shifted to kiln based baking (Roux, 2015). The use of open firing has petered since then. Technological knowledge transfer related to soils and blends are performed by potter women (Kramer, 1997; Satankar *et al.*, 2018).

Material Properties and Physical Properties

X-Ray fluorescence analysis of the cruse illustrates SiO₂(57.87%), Al₂O₃(17.55%), CaO(2.25%) and Fe₂O₃ as major constituents of the off-white cruse. High Na₂O content in off-white cruse supports the salty nature of the soil used in off-white pot manufacture. MgO is about 3.14% in off-white cruse compared to 2.82% in red cruse imported from neighboring state of Gujarat due to aesthetic appearance.

Fourier Transform Infrared (FTIR) spectra in **Fig. 11** showed the appearance of quartz (794, 690 and 460 cm⁻¹), iron oxides (583 cm⁻¹–521 cm⁻¹) and Si-O stretching (1019 cm⁻¹) off white water cruse. The pronounced character of calcite spectra (1440 cm⁻¹) in the IR curve indicates that cruse was not fired above 800°C. The presence of salt in local soil helps the cruse to be baked at comparatively low temperature.

From **Fig. 12**, a non-linear variation of compressive strength as a function of cruse height is observed. The shape of the cruse can be modeled using the information of cruse height. Further the cruse thickness would vary as an antithesis to shape of the cruse (Satankar *et al.*, 2018).

Cooling Studies

The graph in **Fig. 13** shows water cooling studies with the off-white cruse and red cruse during the first week of August (with a outside dry bulb temperature of 36°C). Considerable cooling is obtained while using fully filled off-white cruse as compared to red cruse.

Fig. 11 FTIR Spectra of off-white water cruse.

Fig. 12 Strength as a function of the height of the off-white cruse.

SCMI Ceramics for Water Filtration

A uniform mix of sawdust and salty clay is taken in equal volumes to form the basic mixture required for manufacturing ceramic water filters. Water equal to seventy percent by volume of imingle is added and manual mixing is performed to form the green composite which is further shaped as disks as shown in [Fig. 14\(d\)](#). The disks are kept overnight in a moist cloth covering. The disks are press-formed to frustum shape using a 30 ton press.

Fig. 13 Water temperature profiles within the distinct cruse during August at Jodhpur.

Fig. 14 Steps for the manufacture of the ceramic water filter at Banad village, Rajasthan.

The dimensions of the green ware thus formed were set according to a commercially available plastic bucket of 38 cm height. The green ware thus formed has to be kept for 2 days in ambient conditions and then cured under direct sunlight for 3 days.

Once cured, the green ware is baked in a vertical open hearth furnace (circular shape) of a minimum 5 ft radius and 5 ft height (Roux, 2015). This updraught baking furnace was introduced in Jodhpur in 1960s (Roux, 2015). The green wares were kept 2 ft above the ground in inverted position while baking (Roux, 2015; Ravi *et al.*, 2007). The local potters informed that pure clay flower vases were baked at very high temperatures (800–900°C) using a similar arrangement. These temperatures are similar to those set in factory mode sintering of ceramic water filters (Yakub and Soboyejo, 2013; Plappally *et al.*, 2011a,b). The ceramic water filters thus baked are locally named G Filters (Gupta *et al.*, 2016).

Characterization of Ceramics

Fig. 15(a) shows the microstructure of fired ceramics for water filtration. The scanning electron microscopic image Fig. 15(a) showcases the presence of heterogeneous pore distribution over the clay matrix. The pore size distribution range and porosity

Fig. 15 (a) Surface morphology of Ceramics and (b) Pore size distribution in the Ceramics.

correlations are shown in [Fig. 15\(b\)](#). It can be inferred that the high frequency of porosity is contributed by the pores in the range between 0.02 and 5 microns. This porosity range is at par with the average porosity values of frustum shaped ceramic water filters manufactured at other parts of the globe using a factory mode.

Microbial Removal Efficacy

E. coli (*Escherichia coli*) is an indicator bacterium for occurrence of bacterial pathogens and for fecal contamination ([Brown et al., 2008](#); [Plappally et al., 2011a,b](#)). The *E. coli* filtration experiments were performed on the three separate ceramic water filters manufactured at Banad, Sar and Salawas in Jodhpur District, Rajasthan. Locally these water filters are known as G Filter. The contaminated water when filtered through these devices provided a log removal in the range 2.5–2.8 ([Gupta et al., 2018](#)). These tests adhered to ISO 9308–1:2014 framework ([Paulinus Chigbu, 2007](#)). The contaminated water suspension was similar to the contamination level (10^6 – 10^8 cells/ml) observed in the Yamuna river, India ([CPCB, 2012](#)).

Predicting Flow Through Frustum Shaped Ceramic Water Filters

Using geometrical extension of Darcy's porous flow model

For any porous media, Darcy's Law states that flow rate (Q) is directly proportional to change in pressure head (ΔP), cross-section area of flow and inversely proportional to the thickness t of the media. The law is valid as long as flow is laminar. The Darcy's law may be expressed as

$$Q = -kA\Delta P / \mu t \quad (1)$$

Here k is the intrinsic permeability of the porous media, A is the surface area (of porous media of thickness t) through which the transport of water or fluid may occur and ΔP is the head of water or fluid column above the percolating surface. The Darcy's law for water flow through porous media will change with temperature. At 25°C the density of water is 999.041 Kg/m³ and viscosity takes value 8.935e–4 Pa.s while at 40°C, density of water will be 989.418 Kg/m³, and viscosity will become 6.533e–4 Pa.s.

The flow rate through such a porous media with a frustum shape as shown in [Fig. 16](#) will be expressed as

$$Q_{total} = Q_{base} + Q_{sides} \quad (2)$$

Flow through the surface with radius R_2 and a base thickness of t_{base} is expressed as

$$Q_{base} = \frac{k}{\mu t_{base}} \pi R_2^2 \rho g h \quad (3)$$

The variable flow through the sides of the slanted side frustum surface with a length l and thickness t_{side} is expressed as

$$Q_{side} = \frac{k}{\mu t_{side}} \int_0^h \rho g (h - z) \times 2\pi(R_1 + z \tan \theta) \frac{dz}{\cos \theta} \quad (4)$$

Using information on constituent raw materials

Percolation through frustum shaped ceramic water treatment filters had been theoretically analyzed by several authors ([Plappally et al., 2009](#)). [Plappally et al. 2009](#) outlined a simple multi-parameter empirical model to characterize the percolation

Fig. 16 Schematic of the geometry frustum shaped water filter.

through the filter manufactured with known volume of material constituents. This prediction model is given by

$$G = \frac{X_a}{Z} = 11.4 \times X_a^{0.32} X_b^{-3.02} \quad (5)$$

Here, X_a and X_b represent time and volume fraction of sawdust respectively. Z is the cumulative discharge at any time t .

Using information of electro-kinetic parameters

The electro-kinetic properties of drinking water are important since solute fluxes travelling across frustum shaped ceramic water filter depend on thermo-osmosis, capillary osmosis, electro-osmosis, and time. Percolation flux Q (l/h) may be expressed in terms of these parameters (Plappally *et al.*, 2010),

$$Q = a + bp_1 - cp_2 - dp_3 - ep_4 - fp_5 \quad (6)$$

where p_1 is the ratio of change of turbidity and pH at a specific time before and after a filtration event, p_2 is the change of turbidity before and after the filtration event, p_3 is the change in temperature before and after filtration event, p_4 is the change of electrical conductivity measured before and after the filtration event, and p_5 is the time. This provides a non-equilibrium thermodynamic viewpoint to prediction of flow (Plappally *et al.*, 2010).

Strength of Ceramics

The compressive strength of the G Filter material is a polynomial function of density of the material (Gupta *et al.*, 2018). The density of the material ranges between 2.5 and 2.7 gm/cm³. Compressive strength of the filter material ranges from 5.5 to 9.5 MPa (Gupta *et al.*, 2018). The strength of the material does not diminish during point-of-use water filtration for a continued use of more than 3 months (Gupta *et al.*, 2016).

Local potters also add marble powder in small volume to improve the compressive and flexural strength of these filtration materials. Marble mines are spread all across western Rajasthan which are the source of powdered marble. It is found that this modification to G filter makes them efficient in removing arsenic from contaminated drinking water apart from bacterial contaminants (Kaurwar *et al.*, 2018).

Conclusion

The sustainable use of clayey soils and carbonaceous matter found in Western Rajasthan has been discussed. The blend of equal volume fraction of clayey soils and carbonaceous matter (horse dung) is used in construction of traditional aesthetic shelves within households of this region. The development of flexural strength for such an immingle when saturated with water was found to improve with time. Composites of equal volume fraction of clayey soils and carbonaceous matter (animal dung) can therefore be considered good candidates for use as a medium to fertilize the soil.

Cruse used in this region for water storage have comparatively better water cooling characteristics that imported cruse from neighboring states. Salty soils of this region abundant in Mg and Ca compounds help in production of sustainable off-white cruse covered with amorphous off-white Mg and Ca oxides. Compressive strength of the cruse is a function of its shape.

Another sintered product analyzed in this article is the local ceramic water filter named the G filter. The immingle of equal volume fraction of clayey soils and carbonaceous matter (sawdust) is used as raw materials. Local potter household processes and sinters this device at their premises. Flow through these devices can be modeled geometrically, electro-kinetically and also as a function of constituent raw materials. The water filters showcased good bacterial contaminant removal.

Introduction

The term, 'sustainability' means conservation of an ecological balance by avoiding depletion of natural resources, i.e., it is the endurance of systems and processes. In ecology, sustainability is the property of biological systems to remain diverse and productive indefinitely. Sustainable development is the organizing principle for meeting human developmental goals without affecting/harming the natural systems upon which the economy and society depend. The preferred result is a state of society where the resources continue to meet human needs (for healthy living) without undermining the integrity and stability of the natural systems. We all know that water is the most important element for the survival of living beings; life on earth cannot exist without water. While nearly 70% of the earth's surface is covered with water only 2.5% of it is in the form of fresh water. Fresh water contains very low amount of dissolved salt and is naturally occurring water on earth's surface in ice caps and glaciers (constitutes over 68% of fresh water), ponds, lakes, rivers and swamps (constitutes about 0.3% of fresh water) and around 30% is found in the form of ground water. Even less than 3% of the water on the earth is in the form of fresh water, most of that are inaccessible. Of all the water on earth, more than 99% is unusable by humans and many other living things (Shiklomanov, 2000; Korzoun and Sokolov, 1978). Hence, it is crucial to utilize the accessible fresh water in a sustainable manner. However, one of the most badly affected from human action is water resources. There are numbers of human activities which are continuously destroying the ecological balance and polluting the water resources; industrial runoff, landfills, construction runoff, dumping of waste materials are some of them.

Due to their good solubility in water, synthetic dyes are one of the most common water pollutants that are found in industrial wastewater. Synthetic dyes are extensively used in many industries including paper, textile, plastic, cosmetic, food, concrete etc. More than 10,000 different dyes and pigments are used industrially and 0.7 million tons of synthetic dyes are produced each year all over the world (Meyer, 1981; Zollinger, 2003). In India, about 80% of the total 130,000 tons of dyestuff production is consumed by the textile industry alone (Naik *et al.*, 2013). These industries release wastewater containing residual dyes which are not biodegradable. During dyeing process around 10%–15% of the dye lost in the effluent (Guivarch *et al.*, 2003; Bandara *et al.*, 1996). With the increased use of a wide variety of dyes, pollution by dye wastewater is becoming increasingly alarming. Around 60% of the dyes are used in textile industry and most of them are based on azo dyes. Some of their precursors and reaction products are carcinogenic (e.g., benzidine, 3,3'-dimethoxybenzidine, 3,3'-dimethylbenzidine based azo dyes) (Guivarch *et al.*, 2003; Golka *et al.*, 2004; Brown and De Vito, 1993), therefore treatment of the effluent containing these are very important as they can create serious health issues for humans as well as for aquatic species. Most of effluent wastewater is coming from textile industries due to a more consumption of water for its different wet processing operations, e.g., for an average sized textile mill 200 L water is required for processing 1 kg of fabric per day. According to the World Bank assessment, around 20% of the industrial effluents are generated during textile dyeing and finishing treatment given to a fabric (Kant, 2012).

Color is the first contaminant recognized in wastewater. This discharged wastewater is the origin of some serious environmental problems (e.g., destruction of various life forms, consumption of dissolved oxygen in the water sources etc.). These color effluents also limit the photosynthetic action by restricting the sunlight penetration. Ecological and Toxicological Association of the Dyestuffs Manufacturing Industry (ETAD) was established in the year 1974 with an aim to minimize possible negative impacts of the use of synthetic organic colorants on health and environment. According to the ETAD survey more than 90% of over 4000 tested dyes had LD₅₀ (a lethal dose that kill 50% of the test population) value greater than 2×10^3 mg/kg (Shore, 1996). International organization for standardization has made rules more stringent. For the removal of organic pollutants such as dyes, technological systems have been developed. ISO 14001, October 1996 and the latest environmental management systems is guided in ISO 14001:2015.

Water is a finite and irreplaceable resource that is fundamental to human well-being. It is only renewable if well managed and having a balanced ecosystem. Hence, we need to come up with alternative methods in which we can treat the waste water released from the different sources. Photocatalysis is one of the ways which can help us in the waste water treatment in an efficient way. In this article, we aim to discuss the pathways/solutions that have been carried out for the treatment of waste water and pollutants (which are directly or indirectly affecting the environment and all the living beings).

Methodology for Waste Water Treatment

Several methods which have been used for the wastewater treatments can be broadly classified in three categories (i) chemical (ii) physical (iii) biological (Robinson *et al.*, 2001). The detailed branching and sub-divisions has been schematically shown in Fig. 1.

Fig. 1 A flow chart illustrating various methods used in the wastewater treatment.

Chemical Process: Chemical methods include coagulation or flocculation techniques combined with flotation and filtration, electroflotation, electrokinetic coagulation, oxidation methods (Gupta *et al.*, 2012; Holkar *et al.*, 2016; Robinson *et al.*, 2001) etc. This is often considered as one of the robust ways of removing color from the wastewater. Amongst all chemical processes, oxidation method is the most commonly used chemical decoloration process owing to its easy application process. This method is further categorized into chemical oxidation and advance oxidation process (AOP). Both these methods has the ability to degrade chemical dyes, pesticides etc. either partially or completely under ambient conditions (Holkar *et al.*, 2016). These AOP process can further be classified into photocatalytic oxidation (use of light for activation of catalyst) and fenton chemistry suitable for treating wastewater which are resistant to biological treatment (Holkar *et al.*, 2016).

Physical Process: Physical methods widely used for wastewater treatments include membrane-filtration processes (nanofiltration, reverse osmosis, electrodialysis etc.) and adsorption techniques (Gupta and Suhas, 2009; Robinson *et al.*, 2001; Holkar *et al.*, 2016). The major disadvantage of the membrane processes is that they have a limited lifetime before membrane fouling occurs and the cost of periodic replacement must thus be included in any analysis of their economic viability. Adsorption method provides an alternative way and is superior and efficient than any other physical technique especially if the sorbent is inexpensive and does not require an additional pre-treatment step before its application. Activated carbon is the most efficient adsorbent for a wide range of dyes. Due to difficulty in its regeneration and its high cost makes it less attractive (Robinson *et al.*, 2001) for its utilization at industrial scale.

Biological Process: It is often considered as the cheapest method used for wastewater treatment compared to the chemical and physical methods. Many microorganisms like yeasts, fungi, bacteria and algae are capable to degrade different pollutants and therefore, used for the treatment of industrial effluents (Satyawali and Balakrishnan, 2008; Robinson *et al.*, 2001). On the basis of working environment, biological method can be categorized into aerobic, anaerobic, anoxic, facultative or a combination of these. Their application is often restricted because of technical constraints. Biological treatment requires a large land area and is constrained by sensitivity toward diurnal variation as well as toxicity of some chemicals and limited flexibility in design and operation (Bhattacharyya and Sarma, 2003). Biological treatment is incapable of obtaining satisfactory color elimination with current conventional biodegradation processes. Moreover, although many organic molecules are degraded, many others are recalcitrant due to their complex chemical structure and synthetic organic origin (Robinson *et al.*, 2001; Kumar *et al.*, 1998).

Existing waste water treatment technology such as electrochemical oxidation, coagulation or adsorption do not completely eliminate the pollutants and lead to creation of a more concentrated pollutant-containing phase (Padmanabhan *et al.*, 2006). Other water treatment methods such as filtration, sedimentation, membrane and chemical technologies involve high operating costs and has the potential risk of generating toxic secondary pollutants into the ecosystem (Gaya and Abdullah, 2008). Chlorination has been the most commonly and widely used disinfection process. The disinfection by-products generated from chlorination are mutagenic and carcinogenic to human health (Yang and Cheng, 2007). These have led to the rapid research and development in the field of advanced oxidation process to make improvement in oxidative degradation of the organic compound dispersed or dissolved in aqueous media. Among them heterogeneous photocatalysis is attracting researchers because of its high efficiency in degrading most of the organic pollutants, an exhaustive list has been illustrated in the report by Blake (2001).

Photocatalysis

Photocatalysts are the materials which promote reaction in the presence of light and not get consumed in the overall reaction. Some of the characteristics of a good photocatalysts are (a) being photoactive (preferably visible light active) (b) chemical/biochemical inertness, (c) photostability (i.e. not liable to photo-corrosion), (d) nontoxicity (Bhatkhande *et al.*, 2002) etc. The possible reasons which may be assigned to photocatalysis gaining high importance in wastewater treatment are as follows (Bhatkhande *et al.*, 2002):

- (1) Illustrating total mineralization of most of the organic pollutants,
- (2) Ability to operate in ambient temperature,
- (3) No disposal issues (in water),
- (4) Pathways for an economic and environmentally-friendly solution.

Fundamentals and mechanism of photocatalysis

Photocatalysts in general operate through the principal of band gap (and interactions involving the same), i.e., different classes of semiconductor materials cater to the need of various photocatalytic applications. Traditionally, semiconductors exhibit an empty energy region in which no energy levels are available to promote the recombination of an electron and hole produced by photoactivation in the solid which is unlike metals, i.e., having a continuum of electronic states. For a semiconductor to be a photo-chemically active, the redox potential of the photogenerated conductance band electron must be sufficiently negative and photogenerated valence band must be sufficiently positive so that electron can reduce the adsorbed O_2 to superoxide and hole can generate the OH radicals (most potent oxidizing agents) which will then subsequently oxidize the organic pollutants (Gaya and Abdullah, 2008; Bhatkhande *et al.*, 2002; Mills and Le Hunte, 1997; Chong *et al.*, 2010).

On irradiation of light (Ultraviolet or Visible) absorption of photon takes place in semiconductor materials and excites an electron (e^-) from the valence band to the conduction band if the photon energy ($h\nu$), equals or greater than the band gap of the semiconductor/photocatalyst. During excitation of an electron (e^-), simultaneously, a hole (h^+ , positive charge) is generated in the valence band (schematically shown in Fig. 2).

On the generation of electron-hole (e^-h^+) pair, mainly two possibilities exists (i) recombination of electron and hole pair producing thermal energy in the absence of suitable scavenger or surface defect state to trap the electrons (ii) prevention of recombination and participation in redox reactions with the compound adsorbed on the photocatalyst. Although, the lifetime of an e^-h^+ pair is few nanoseconds (Bussi *et al.*, 2002), it is still long enough for initiating/promoting redox reactions. Generally, the electron can be offered to an electron acceptor like a metal ion whose redox potential is more positive than the photocatalyst band gap or to an oxygen molecule to form a superoxide radical. In the same way, a hole oxidizes water to form hydroxyl radicals (which subsequently initiate a chain of reactions leading to the oxidation of organics). The same can also combine with the electron from a donor species, depending on the mechanism of the photoreaction. Thus, the series of chain oxidative reductive reactions that occur at the photon activated surface can be postulated as follows (Chong *et al.*, 2010):

Fig. 2 Schematic diagram depicting mechanisms that take place during photocatalysis.

Here, e_{TR}^- and h_{TR}^+ in Eq. (5) represent the surface trapped conductance band electron and valence band hole respectively. Furube *et al.* (2001) worked on TiO_2 and reported that these trapped carriers are surface bound and do not recombine immediately after photon excitation. For the successful functioning of photocatalysis, recombination of electron-hole needs to be delayed. In the absence of an electron scavenger, they recombine (Eq. (5)) in nanoseconds and negatively affects the efficiency of photocatalytic reaction. Eq. (6) depicts prevention of recombination of electron-hole pair in the presence of oxygen and allowing the formation of superoxide radical ($O_2^{\bullet -}$) further lead to the formation of $HO_2^\bullet$; a radical with scavenging property (Chong *et al.*, 2010).

Kinetics of photocatalytic degradation

For the industrial need of scaling up of the process, it is crucial to study the kinetics and mechanisms of the photodegradation and/or photo-disinfection rate of the water contaminants. Proper operation of kinetic models for the elucidation of experimental data allows the design and optimization of photoreactor framework with adequate capacity and minimal non-illuminated reactor volume. Most of the kinetic studies have been performed for the TiO_2 materials in the past (Okamoto *et al.*, 1985; Fox and Dulay, 1993; Robert and Weber, 1998; Khanchandani *et al.*, 2016; Xu *et al.*, 1999); some of them have been highlighted here (in Section "Recent Research Works in Related Field" and Table 1). Most of these studies concluded that, the initial rate of degradation of pollutants fits a Langmuir-Hinshelwood (L-H) model. Generally, two main reaction mechanisms have been proposed for heterogeneous catalysis, namely Langmuir-Hinshelwood and Eley-Rideal (Ertl, 1994; Rademann, 1990). Baxter and Hu (2002) studied CO oxidation on Pt(111) and investigated the suitability of L-H mechanism over Eley-Rideal ones. The authors concluded that reaction barriers for Langmuir-Hinshelwood mechanisms actually tend to be higher than those for Eley-Rideal ones. They also provided an explanation of why the Langmuir-Hinshelwood is preferred in the vast majority of surface catalytic reactions, despite its higher energy barrier.

The L-H model is strictly surface area dependent and works on the following basic assumptions (Fox and Dulay, 1993):

- (1) Number of surface site is fixed at equilibrium;
- (2) Only one substrate may connect at each surface site;
- (3) Heat of adsorption by the substrate is same for each site and is independent of surface exposure;
- (4) There is no interaction between adjacent adsorbed molecules;
- (5) The rate of surface adsorption of the substrate is greater than the rate of any succeeding chemical reactions;
- (6) No irreversible blocking of active sites by binding to product occurs.

With all these assumptions L-H kinetic scheme can be shown as (Mills *et al.*, 1993; Fox and Dulay, 1993);

$$r_t = \frac{-dC}{dt} = \frac{k_r K_{ads} C}{1 + K_{ads} C} \quad (9)$$

where C is the initial concentration of pollutant, r_t is the rate of reaction (changes with time), k_r is the reaction rate constant ($\text{mg L}^{-1} \text{min}^{-1}$), K_{ads} is the equilibrium or Langmuir adsorption constant of the pollutant molecule on the catalyst surface (L mg^{-1}). The initial rate of reaction as a function of C_0 can be given by:

$$r_0 = \frac{k_r K_{ads} C_0}{1 + K_{ads} C_0} \quad (10)$$

Values of K_{ads} and k_r can be obtained by linearizing the Eq. (10) as follows:

$$1/r_0 = 1/k_r + 1/k_r K_{ads} C_0 \quad (11)$$

On integrating Eq. (9) between the limits: $C=C_0$ at time, $t=0$ and $C=C$ at $t=t$, we will get:

$$\ln \frac{C_0}{C} + K_{ads}(C_0 - C) = k_r K_{ads} t \quad (12)$$

If $K_{ads} C \ll 1$, then integrating Eq. (9) between the limits: $C=C_0$ at $t=0$ and $C=C$ at $t=t$, L-H expression can be reduced to

$$-\ln \frac{C}{C_0} = k_{app} t \quad (13)$$

When the organics concentration is low (in mM), an "apparent" first-order rate constant Eq. (13) could be expressed where (apparent rate constant, $k_{app}=k_r K_{ads}$). The term k_{app} (min^{-1}) is only served as a comparison and description for the photocatalytic reaction rate in the reactor system (Chong *et al.*, 2010). The linearity of a plot of $1/r_t$ versus $1/C$ of the Eq. (9) tests the validity of the L-H model, where $1/k_r$ can be taken as the 'Y-intercept' and $1/k_r K_{ads}$ is the slope (Fox and Dulay, 1993).

The popularity of the L-H model is clearly evident by the number of research papers used this model over the years; a histogram depicting the trend is shown in Fig. 3. Around 4400 papers have appeared (1970–2016) out of which around 3600 have appeared in last 20 years (1996–2016). Many works have shown good linearity (Cunningham and Al-Sayyed, 1990; Al-Ekabi and Serpone, 1988;

Table 1 Degradation of pollutants using photocatalysts

Photocatalysts	Pollutants	Operating Conditions	Highlights of work	Ref.
TiO ₂ (Degussa P-25)	Alizarin S (AS) Crocein Orange G (OG) Methyl Red (MR) Congo Red (CR) Methylene Blue (MB)	● NaOH and HNO₃ were used for pH adjustment ● UV light for excitation source	Feasibility of TiO ₂ was tested successfully for complete degradation of structurally different dyes either anthraquinonic (AS), or azoic (OG, MR, CR) or heteropolyaromatic (MB).	Lachheb <i>et al.</i> (2002)
TiO ₂ /Carbon fibers (T/CF)	Acid Orange 7 (AO7)	● working pH – 7 ● UV light was used as an excitation source	Low exciton recombination, numerous activated sites, high surface areas and hydroxy content of T/CF demonstrated functional property with enhanced degradation efficiency.	Lin <i>et al.</i> (2015)
TiO ₂ /CuS core/shell nanostructure	Methylene blue	● Visible light was used as an excitation source	Broad potential in the photocatalysis domain for the design of a visible light functional and reusable core/shell nanostructures photocatalyst.	Khanchandani <i>et al.</i> (2016)
Poly(diphenylbutadiyne) (PDPB)	Methyl Orange Phenol	● Both Visible and UV light were used as an excitation source ● Solution was bubbled with oxygen at fixed flow rate	PDPB nanofibres exhibited excellent photocatalytic activity compared to bulk PDPB. First experimental evidence of the photocatalytic activity of conjugated polymer nanostructures under visible light for water decontamination.	Ghosh <i>et al.</i> (2015)
BiPO ₄	Methylene blue	● UV light was used as an excitation source	BiPO ₄ photocatalytic activity was found twice better than that of Degussa P-25 TiO ₂ . The inductive effect of PO ₄ ^{3–} helped the e [–] /h ⁺ separation, leading to its excellent photocatalytic activity.	Pan and Zhu (2010)
ZnS-GR (Reduced grapheme oxide)	Organic compounds (alcohols or alkenes)	● Visible light was used as an excitation source	The ZnS/GR nanocomposites were confirmed to work for selective aerobic oxidation of alcohols and alkenes under ambient conditions.	Zhang <i>et al.</i> (2012)
Ag ₂ O	Methyl Orange	● Visible light was used as an excitation source	The Ag ₂ O photocatalyst was reported as a new candidate the removal of hazardous organic materials from wastewater; issues persisted with its preparation (with large specific surface areas and high pore volumes)	Wang <i>et al.</i> (2011)
Sb ₂ S ₃	Methyl Orange	● Visible light was used as an excitation source	Photodegradation ratio of methyl orange was up to 97% after 30 min of irradiation, which was much better than that of CdS and TiO _{2-x} N _x under the same condition	Sun <i>et al.</i> (2008)
Ag-AgBr	Methyl Orange	● Visible light was used as an excitation source	The as-prepared Ag-AgBr photocatalyst was reported for methyl orange dye degradation (more than 83% within 2 min of sunlight irradiation)	Kuai <i>et al.</i> (2010)
CNT-pillared graphene oxide (GO) and reduced graphene oxide (RGO)	Rhodamine B (RhB)	● Visible light was used as an excitation source	3D CNT-pillared GO and RGO nanostructures exhibited an excellent visible light photocatalytic performance in degrading RhB dye in water	Zhang <i>et al.</i> (2010)
g-C ₃ N ₄ /Ag ₃ PO ₄	Methyl Orange	● Scavengers for [•]OH, h⁺ and O₂^{•–} introduced ● Visible light was used as an excitation source	The as-prepared graphitic-C ₃ N ₄ /Ag ₃ PO ₄ hybrids exhibited excellent photocatalytic activity on the decolorization of methyl orange, which was superior to those of pure g-C ₃ N ₄ and Ag ₃ PO ₄ under visible-light irradiation (> 440 nm)	Katsumata <i>et al.</i> (2014)
BiOCl/BiOI	Methyl Orange Rhodamine B (RhB)	● Visible light was used as an excitation source	20% BiOCl/BiOI composite illustrated highest photocatalytic activity for the decomposition of MO and the 70% BiOCl/BiOI composite exhibited the highest photocatalytic activity on the degradation of RhB.	Li <i>et al.</i> (2011)
ZnS-GR (Reduced grapheme oxide)	Organic compounds (alcohols or alkenes)	● Visible light was used as an excitation source	The ZnS/GR nanocomposites were reported promising photocatalysts for selective aerobic oxidation of alcohols and alkenes under ambient conditions.	Zhang <i>et al.</i> (2012)
Co ₃ O ₄ /BiVO ₄	Phenol	● Visible light was used as an excitation source	The composite photocatalyst exhibited highest efficiency at 0.8 wt% cobalt content, 96% reduction in the concentration of phenol was noted in 180 minutes.	Long <i>et al.</i> (2006)

(Continued)

Table 1 Continued

<i>Photocatalysts</i>	<i>Pollutants</i>	<i>Operating Conditions</i>	<i>Highlights of work</i>	<i>Ref.</i>
ZnO	Acetaldehyde	● Hg–Xe lamp ($\lambda=365$ nm) was used as an excitation source	Photocatalytic activity noted to be strongly dependent on powder crystallinity than the surface area.	Li and Haneda (2003)
TiO ₂ (Degussa P-25)	Pesticide derivative triclopyr and daminozid	● Medium pressure mercury lamp was used as an excitation source	The pesticide derivative triclopyr was found to degrade faster as compared to daminozid. Addition of electron acceptors enhanced the degradation rate of the pollutants.	Qamar <i>et al.</i> (2006)
Graphitic carbon nitride	4-chlorophenol and phenol	● Visible light irradiation from a 300 W Xe lamp	The photocatalysts could induce the formation of reactive oxy-species such as H ₂ O ₂ , ·OH and O ₂ ^{·-} /OOH under visible light irradiation, while keeping a high photocatalytic reactivity during recycling operations.	Cui <i>et al.</i> (2012)
CuO	4-Nitrophenol	● No external source of light, normal light only	Remarkable activity was shown by CuO nanorods (in presence of sodium borohydride) as the complete degradation of 4-NP was observed in just fifteen minutes.	Kumar and Chowdhury (2017)

Fig. 3 Histogram showing number of papers published related to Langmuir-Hinshelwood (Year 1996–2016). (Searched phrase: Langmuir-Hinshelwood).

Hsiao *et al.*, 1983) in such plots but unfortunately, this fit cannot be taken as a guaranteed proof of pre-adsorption since an identical analytical formulation of the rate law can be obtained even for reactions occurring entirely within a homogeneous phase (Turchi and Ollis, 1990). These cases pose restrictions and associated concerns for overall general applicability of L-H kinetics to any given photocatalytic degradation process. Cunningham and Al-Sayyed (1990) have measured dark Langmuir adsorption isotherms for TiO_2 , for a variety of different organic pollutants and found them to be significantly smaller than the values of K_{ads} obtained from plots $1/r_v$ versus $1/[C]$. It appeared more likely that the value of K_{ads} derived from a kinetic study was not directly equivalent to the Langmuir absorption coefficient (for pollutants on TiO_2). Alternative kinetic approaches/models have been worked out by researchers; some of the important ones are discussed below:

(1) Pseudo steady-state approach:

Ollis (2005) has also shown that reactant adsorption is not constant in photocatalytic reaction. This is contrary to one of the assumptions of the L-H kinetic approach. As photocatalysis routinely involves the initial generation of reactive intermediates like holes, free electrons and hydroxyl radicals; their reactivity with reactants in the solution cannot expect reactant adsorption to be equilibrated. Hence, the slow rate controlling surface step inherent in the original L-H formulation is not valid in photocatalysis. So, a pseudo-steady state approach was suggested by the author to be utilized in the kinetic equation for reactant itself, not just for the active intermediates (Ollis, 2005).

(2) Direct-Indirect (D-I) model:

K_{ads} is dependent on the illumination flux (ϕ , i.e., photons per unit time reaching a surface). This also contradicts the L-H model premise according to which adsorption/desorption of reactants is maintained at equilibrium under illumination. The L-H model does not define the k_r dependence on ϕ , so that by itself is unable to predict any existing relationship between ϕ and the reaction rate. To alleviate such problems, an alternative kinetic approach was given by Monllor-Satoca *et al.* (2007). This is known as the "Direct-Indirect" (D-I) model, which is based on the degree of electronic interaction of the semiconductor surface with dissolved reactant molecules. Since a primary assumption of the L-H kinetic model is the requirement for surface pre-adsorption, a broad range of reaction rates can be expected from differences in adsorptive affinity of different substrates on a given semiconductor surface.

(3) Chemometric approach:

This approach was suggested by Sleiman *et al.* (2007) specifically for TiO_2 and its related systems based upon the surface response modeling. In this, two-step process, the first step involved investigation and establishment of the relative influence of the experimental factors (TiO_2 and dye concentration, pH, temperature, light flux and oxygen concentration) and their possible interactions. The second step was left for the identification of possible degradation products as well as the evaluation of the total mineralization during the process.

Kinetics of water purification photosensitized by photocatalyst is dependent on many factors as discussed below in the following section.

Effect of operating parameters on photocatalysis reactions

- Intensity and Wavelength of Light:

The photocatalytic reaction rates are dependent on the intensity of the light; an enhanced response with increase in light intensity during photocatalytic degradation was reported (Qamar *et al.*, 2006). The nature or form of the light did not seem to affect the reaction pathways (Stylidi *et al.*, 2004). In other words, the band-gap sensitization mechanisms do not seem to influence the photocatalytic degradation pathways, as a whole. Rincón and Pulgarín (2003) reported that the residual disinfecting ability of the photocatalyst largely depends on the duration of light intensity (without any temporal pauses). The authors examined the effect of light intensities (at 400 and 1000 W/m²) on bacterial mortality and regrowth, and found that the higher intensity (without any breaks) can cause irreversible damage to the *E. coli* bacteria's. In the sporadic light irradiations with constant interruptions, the bacteria were noted to regrow during the subsequent 24 or 48 h. Light sources emitting different range of wavelength was reported to have significant impact on the photocatalytic response rate and also noted to depend upon the type of photocatalysts utilized, crystalline phase, anatase-to-rutile phase transitions (in case of TiO₂) etc. (Chong *et al.*, 2010).

- Photocatalyst Loading:

Heterogeneous photocatalytic responses are known to demonstrate corresponding increment in photodegradation with catalyst loading. In any given photocatalytic application, optimum catalyst concentration must be determined, as over-abundance have a negative impact on the activity of the photocatalytic process due to unfavorable light dispersing and decrease of light infiltration (Gaya and Abdullah, 2008). The assurance of photoreactor distance across is critical in retaining the optimum photons successfully; the water stream hydrodynamics is also noted to be crucial for efficient working of the photocatalytic system (Malato *et al.*, 2009).

- Effect of pH:

pH is one of the most important operating parameters in heterogeneous photocatalytic water reactions that control the charge on the catalyst particles, size of catalyst aggregates and the positions of conductance and valence bands (Haque and Muneer, 2007; Chong *et al.*, 2010). The pH of a system has the potential to influence the surface charge and also the ionization state of the substrate (and hence the adsorption) (Kosmulski, 2006).

- Effect of Anions and Cations:

Abdullah *et al.* (1990) carried out a thorough investigation on the impact of anions on the rate of photo-mineralization of organic pollutants (salicylic acid, aniline, and ethanol) in the presence of TiO₂. The authors concluded that perchlorate and nitrate ions have little/no impact, while sulfate, chloride, and phosphate (at fixations > 10⁻³ mol dm⁻³) could diminish the rate of photomineralization by 20%–70% because of their retention at the oxidation locales on the TiO₂. Wei *et al.* (1990) examined the impact of cations, for example, Fe³⁺ and Cu²⁺ on the photocatalytic degradation of phenol. Fe³⁺ depicted an enhancement in initial phenol removal from 23% to 33%, whereas a negative impact was observed for Cu²⁺ case. However, in the presence of H₂O₂, an increase in the rate of phenol oxidation was noted for both the cases.

- Effect of Surface Area:

Photocatalytic degradation process is influenced by adsorption of pollutants on the catalysts, thus the impact of surface area is critical in entire process. As the particle size diminishes to nanoscale, the increase in the surface area foster the adsorption activities thereby improving the photocatalytic degradation rate. Degan and Tomkiewicz (1993) showed that TiO₂ aerogels with a surface area of 600 m² g⁻¹ depicting superior activity than commercial Degussa P-25 (with surface area of 55 m² g⁻¹).

- Effect of Reaction Temperature:

Generally, the increase in temperature enhances recombination of charge carriers along with the desorption of adsorbed reactant species, thereby resulting in a decrease of photocatalytic activity (Gaya and Abdullah, 2008). For a TiO₂ system at a reaction temperature (for photocatalytic activity) greater than 80°C, the adsorption of the reactants was disfavored, leading to the reduction of photocatalytic activity. At a very low reaction temperature (down to 0°C), increase in the apparent activation energy was noted. As a consequence, the optimum reaction temperature for photo-mineralization is reported to be in the range 20–80°C (Malato *et al.*, 2009).

- Effect of Dissolved Oxygen:

A critical part in TiO₂ photocatalysis response is to ensure adequate electron scavengers are present to trap the energized conduction-band electron from recombination (Chong *et al.*, 2009). The oxygen does not influence the adsorption on the TiO₂ catalyst surface as the reduction response happens at an alternate location from where oxidation occurs (Malato *et al.*, 2009). The presence of dissolved oxygen is needed for degradation of hydroxyl byproducts, and in the cleavage mechanism of aromatic ring (Wang and Hong, 2000).

Recent Research Works in Related Field

The interest in the area of photocatalysis started with the pioneering work by Honda–Fujishima on water splitting by using TiO₂ electrode in early 1970s (Fujishima, 1972). Plethora of initiatives were taken by the research community during the 1970 and 1980s in the development of semiconductor photochemical cells (Heller, 1981). This is also clearly evident from the number of publications in

Fig. 4 Histogram for number of papers published related to photocatalysis during the period 1996–2016.

the recent years as shown in Fig. 4. Around 43,600 papers have been published (1970–2016); out of which around 43,000 in just 20 years from 1996 to 2016. Some of the important materials that have been explored for the photocatalysis are listed below as follows:

- Titanium dioxide (TiO₂):

TiO₂ has been the most-investigated system for all such cases involving photocatalysis, removal of organic pollutants etc. Frank and Bard (Steven and Bard, 1977; Frank and Bard, 1977) were the first to examine the use of TiO₂ for the environmental application and reported on the decomposition of cyanide (CN[−]) and sulfite (SO₃^{2−}) ions in aqueous solution with the help of xenon light source. TiO₂ emerged as the superior one and the possible reasons were assigned to various factors, e.g., highly oxidizing photogenerated holes, high chemical stability, low cost etc. (Fujishima *et al.*, 2000). The use of TiO₂ (in powder form) for photocatalysis requires its separation from the solution. To immobilize these TiO₂ particles, researchers started using it in thin film form. Sopyan *et al.* (1996) investigated the photocatalytic activity of TiO₂ thin film (on a glass substrate) for the degradation of gaseous acetaldehyde. Larger number of adsorption sites per unit of (true) surface area was traced for the thin film (analyzed in powder form) compared to the degussa P-25 TiO₂ powders, thereby confirming superior photocatalytic activity for film (w.r.t. the powder form). Lin *et al.* (2015) worked on the synthesis of ordered mesoporous titania on carbon fibers via liquid crystal template technique under supercritical conditions. The authors concluded on achieving high photocatalytic activity under UV light (for acid orange 7 degradation) and attributed the same to numerous factors, viz., high surface area, high hydroxyl content, numerous activated sites and low exciton recombination rate. One major disadvantage of TiO₂ system lies in its ineffectiveness in visible light. Anatase TiO₂ bandgap is around 3.3 eV and requires an excitation wavelength, $\lambda < 376$ nm. This spectral regime constitute less than 5% of the solar flux incident at the earth's surface (In *et al.*, 2007). To eliminate this drawback, TiO₂ has been frequently doped with other elements like boron, sulfur nitrogen etc. (Ho *et al.*, 2006; Asahi *et al.*, 2001; In *et al.*, 2007). However, doped TiO₂ materials has their own issues, viz., requirement of an expensive ion-implantation facility, an increase of carrier-recombination centers, thermal instability etc. (Choi *et al.*, 1994; Anpo, 1997).

Hence, the present day goal for researchers is focused on finding more stable, cost effective and industrially viable efficient photocatalysts which can be activated by natural sunlight. Till date, numerous system (Pan and Zhu, 2010; Asahi *et al.*, 2001; Ghosh *et al.*, 2015; Lin *et al.*, 2015; Zhang *et al.*, 2010, 2012) have been tried, some of the important materials are discussed below and other relevant data are compiled in Table 1.

- Zinc oxide (ZnO):

Apart from TiO₂, ZnO is one material which has been heavily explored for photocatalysis (Quintana *et al.*, 2017; Chakrabarti and Dutta, 2004). The greatest advantage of ZnO is that it absorbs large fraction of the solar spectrum and higher quanta of light than TiO₂ (Sakthivel *et al.*, 2003). Although, it is relatively cheaper material than the TiO₂ but belong to the same class of wide band gap semiconductor and also suffers from photo-corrosion upon UV irradiation in solution. To alleviate these issues, number of modifications (e.g., rare earth and/or cationic/anionic doping etc.) has been carried out in ZnO (Lee *et al.*, 2016). Pd doped ZnO (Zhong *et al.*, 2012) has been reported for increased adsorption ability of light and high separation rate of photoinduced charge carriers. Similarly, stronger ultraviolet as well as visible light absorption was induced by the C, N doping and discouragement in e-h pair recombination was reported on doping of C, N and S in ZnO (Yu *et al.*, 2016).

- Bismuth oxyhalide:

Bismuth oxyhalide-based nanomaterials is another system which has received huge attention (Xiao *et al.*, 2012; Song *et al.*, 2010; Jiang *et al.*, 2010; Chang *et al.*, 2010; Zhang *et al.*, 2008; Guan *et al.*, 2013) recently because of their unique layered

structures which endow them with excellent physicochemical properties. Li *et al.* (2014) have worked on bismuth oxyhalide and highlighted some crucial issues in tailoring the layered structure mediated properties of bismuth oxyhalide photocatalysts (such as pH-dependent crystal facet exposure and allied phase transformation mechanisms, facet-dependent molecular oxygen activation pathways etc.). The authors also recommended exploratory suggestions for future research for increasing the photocatalytic performance, as (i) crystal facet engineering to tune the internal electric field intensity in bismuth oxyhalide nanomaterials (ii) controlled synthesis measures to expose high energy crystal facets (iii) investigations on the facet-related redox behavior of bismuth oxyhalide nanomaterials.

- Graphene-based composites/carbon nanotubes (CNTs)/fullerenes:

Graphene, known as the “wonder” material among the research community, has also been used as a grapheme/semiconductor composite photocatalyst (Zhang *et al.*, 2009; Xiang *et al.*, 2012); the main advantages have been highlighted as superior electrical conductivity, large specific surface area and high adsorption rates (Xiang *et al.*, 2012). Zhang *et al.* reported enhanced photocatalytic activity for TiO₂ (P25)-graphene composite under both UV/Visible light in degrading methylene blue compared to the bare TiO₂ (P25) and P25-CNTs with the same carbon content. The authors assigned the performance credit to the synergistic effects of extended light absorption range and efficient charge separation properties (Zhang *et al.*, 2009). Graphene-Bi₂WO₆ composite (synthesized via in-situ hydrothermal reaction using ethylene glycol as a reducing agent) was noted for enhanced photocatalytic activity; complete degradation of rhodamine-B dye was observed in eight (08) minutes in visible light (Gao *et al.*, 2011). No doubt that graphene based composites are promising candidates suitable for designing and fabricating advanced photocatalysts for various applications. However, there are many open issues (e.g., fabrication of large scale defect-free single layer pure graphene sheets, synthesis of high-quality graphene-based nanomaterials, composites etc.) which need considerable attention by the research community, at large. Also, due to the lack of hydrophilic functional groups on the pure graphene sheets, preparation of semiconductor/pure graphene composites has been reported to be challenging (Li *et al.*, 2016). CNTs and fullerenes have been used as a promising adsorbents for the treatment of aqueous solutions contaminated by metals ions as well as reported to be good in treating organic and inorganic pollutants. However, further research is needed to understand and improve the absorption mechanism in these materials (Gupta and Saleh, 2013).

- Other materials for pollutant removal:

α -Fe₂O₃ has been noted for absorption of visible light (~ 560 nm), but the electron-hole (e^- - h^+) charge separation is very short-lived and limits its use as a photocatalyst/photoelectrode (Cherepy *et al.*, 1998). Plasmonic photocatalysts like nanostructured Ag, Au or Cu supported on metal oxides have been reported for broader scope for treatments of pollutants. However, they are considered as expensive options and mechanistic insights are still lacking (Lang *et al.*, 2014). In one of our recent work (Kumar and Chowdhury, 2017), we have tested the applicability of high aspect ratio (nanorods length greater than 100 nm having diameter of 10 nm) copper oxide (CuO) nanorods (synthesized without using any surfactants or templates) for treatments of water pollutants. We chose 4-Nitrophenol (4-NP), one of the most common pollutants traced in industrial effluents usually originating from various chemical plants, e.g., units manufacturing explosives, products for leather treatment, dyestuffs, and agricultural irrigation effluents etc. Remarkable activity was shown by CuO nanorods (in presence of sodium borohydride) as the complete degradation of 4-NP was observed in just fifteen minutes; Fig. 5. Similarly, in another work we illustrated the efficacy of the La³⁺-doped-CeO₂ nanoparticles for the degradation of methylene blue (MB) dye as pollutant. MB is one of the commonly used staining agents that portrays strong resistance to biochemical oxidation. The catalyst nanoparticles degraded MB dye completely in three hours under artificial visible light (shown in Fig. 6).

Nanostructures involving conducting polymers have also been used under visible light for photocatalysis. Ghosh *et al.* (2015) reported good photocatalytic activity for poly-(diphenylbutadiyne) nanostructures prepared by photo polymerization using a soft templating approach; the synthesis process did not involve any sacrificial reagents or metal co-catalysts. They have reported 75% photodegradation of methyl orange in the presence of poly (diphenylbutadiyne) nanostructures after 240 min visible light irradiation. It was shown that the polymer fiber remained stable and retained the morphology and structure even after five photocatalytic cycles. The authors claimed usefulness of this system for the development of semiconducting-based polymers for applications in photovoltaics, self-cleaning surfaces and hydrogen generation.

Issues With the Use of Dye as Model Pollutant

Most of the research works have used dyes as a model for testing the potential of the photocatalytic material. Dyes are commonly used as model pollutants, not only because they are used by numerous industries (Tanaka *et al.*, 2000) but also their degradation concentration can be easily monitored using a spectrophotometer. Table 1 shows the works that have used dye as a pollutant to study the photocatalytic activity. But dye decolorization test for visible light active photocatalysts have number of serious concerns as discussed below,

- (1) Dye sensitization effect:

Dyes can absorb visible light and many of them have an ability to inject an electron into the conduction band of the semiconductor photocatalytic material. This property is widely exploited in dye-sensitized solar cells (DSSC), where dyes are used together with a photocatalyst that is usually a semiconductor oxide such as TiO₂ (Grätzel, 2009). Design of DSSCs

Fig. 5 UV-vis spectra of 4-nitrophenol reduction with NaBH_4 in absence and presence of CuO nanorods (from zero to 15 min); the inset plot depicts the UV-vis spectrum of 4-nitrophenol. The color changes of the mixture (confirming the degradation of 4-nitrophenol) solution over time is also shown. Reproduced by Kumar, K., Chowdhury, A., 2017. Facile synthesis of CuO nanorods obtained without any template and/or surfactant. *Ceramics International* 43 (16), 13943–13947.

Fig. 6 Photocatalytic degradation kinetics plot of MB dye under visible light under different loading of catalysts (0%, 10% and 50% as denoted by the trend lines with 'triangle', 'square' and 'circle' legends). The color change of the solution with continuous decrease in the MB concentration is shown for LC10 and LC50 in the inset images. For the case of LC10 sample, more than 20% degradation was observed within 30 s justifying a non-zero Y-axis start value. Reproduced by Singh, K., Kumar, K., Srivastava, S., Chowdhury, A., 2017. Effect of rare-earth doping in CeO_2 matrix: Correlations with structure, catalytic and visible light photocatalytic properties. *Ceramics International* 43, 17041–17047.

prevents the degradation of dye but this may not be in the case of aqueous suspension of dye and photocatalyst. Hence, it would be difficult to know, whether dye has degraded itself through dye sensitization or by a photocatalyst or under the influence of both the factors (Kamat *et al.*, 1991; Kamat, 1990).

Fig. 7 Photograph of the photocatalytic pilot plant installed in the Wolfsburg factory of the Volkswagen AG (Photo: J. Lohmann, ISFH). Reproduced by Bahnemann, D., 2004. Photocatalytic water treatment: Solar energy applications. *Solar Energy* 77 (5), 445–459.

(2) Dye concentration effect:

Generally, higher the dye concentration higher the adsorption and this may lead to high photocatalytic degradation. But when both the dye and photocatalyst can absorb the light (in visible range) in the same wavelength range, the effect of dye concentration on degradation becomes complex and the photocatalytic degradation may be retarded. Excess dye may shield the photocatalyst from irradiation as they may attenuate the incident light flux available to the system during visible light absorption. This may underestimate the intrinsic visible light activity of the photocatalysts (Bae *et al.*, 2014).

(3) Dye decolorization and mineralization:

Generally, dye decolorization indicates the destruction of chromophore group (the structure which is responsible for the appearance of color in dyes) and may not guarantee the complete mineralization as there is poor correlation between decolorization and total organic carbon removal (TOC) (Vautier *et al.*, 2001). The absorbance monitoring at a single wavelength can be inaccurate as any other compound/s may form during reaction (having a different absorbance wavelength) and that will be reflected in TOC measurement test. Bae *et al.* (2014) have reported similar color removal efficiency for TiO_2 based catalyst on UV and visible light irradiation but TOC removal efficiency was different and it was much higher under UV than the visible light for the same sample.

Despite of numerous advantages and high potential of photocatalysis in waste water treatment, very few photocatalytic reactor has been commercially installed (or in use). Nearly twenty years ago a review by Goswami (1997) discussed on the matter of only two engineering scale demonstrations, one for groundwater treatment in the U.S. and the other for industrial wastewater treatment in Spain. But more installations have recently been put up, mainly based on nonconcentrating collectors. In laboratory and bench-scale experiments, Dillert *et al.* (1999b) have treated biologically pretreated industrial waste water from the Volkswagen AG factories in Wolfsburg (Germany) and Taubaté (Brazil). The results of the experiments, which were executed using the Double Skin Sheet Reactor (DSSR), were promising enough to install a pilot plant in the Wolfsburg factory (shown in Fig. 7) during the summer of 1998 (Dillert *et al.*, 1999a). The flowsheet of a more recent version of this pilot plant which was installed in 2000 is given by Bahnemann (2004). Since 2007, a homogeneous solar photocatalytic CPC plant (100 m^2) for the pretreatment of saline industrial wastewater containing bio-refractory pharmaceuticals is in operation at a Spanish pharmaceutical company (DSM DIRETIL) as shown in Fig. 8. The system is reported to be able to remove 50% of the initial dissolved organic carbon; the remaining 45% can be removed by an aerobic biological treatment (Oller *et al.*, 2007).

One of the primary inclination behind the development of visible light-mediated photocatalytic processes is the need for more environmental friendly chemical processes. The work that has been carried out in this area till date is neither very much economically viable nor so much eco-friendly.

Future Challenges and Prospects

Use of photocatalysts (preferably under visible light) has become more prominent owing to its simplicity in operation and efficiency in removing disinfectants and mineralization aspects. As many other methods transformed the recalcitrant organics to other phases, photocatalysis helps in complete mineralization. All these attributes make them a viable option for waste water treatments. Although some photocatalytic applications (portable depollution systems, self-cleaning windows etc.) are already in the market, it is understandable that development of photocatalysts with improved capability and efficiency will continue to be a trending topic of research in the near future. Titania-based materials seem to dominate this field because of its relatively superior performance and economic factors.

Fig. 8 Partial views of a solar photocatalytic plant used for solar photocatalytic water detoxification. Reproduced by Spasiano, D., Marotta, R., Malato, S., Fernandez-Ibañez, P., Di Somma, I., 2015. Solar photocatalysis: Materials, reactors, some commercial, and pre-industrialized applications. A comprehensive approach. *Applied Catalysis B: Environmental* 170–171 (0), 90–123.

In today's time the use of photocatalysis under visible light faces serious challenges in various directions. The first concern involves the choice and find of a suitable material/s which can prove its versatility for the degradation of a range of hazardous dyes and pigments. Although the initial research in this field started with TiO_2 ; a lot of other materials and composites are being reported on a daily basis as suitable photocatalysts. The main philosophy behind such new materials mostly relates to their suitable band gap (comparable in the visible light wavelength) and its kinetics of degradation. It needs to be realized that both these factors and their assessment may be seriously flawed due to the assumptions or errors in measurements. As discussed before, both the degradation kinetics and band gap measurements need crucial modifications. While the synthesis of new composites (e.g., graphene based) involves serious dispersibility issues; the photocatalysts involving bismuth-based systems poses serious environmental concerns (for it to be used in a large industrial scale). The band gap engineering of these photocatalysts can also be achieved via microstructural modifications (size, shape, texture etc.) and therefore remains as an open arena for further research. At present it seems that, photocatalysts alone may not be able to serve as the panacea for the degradation of dyes, pigments and pollutants since the lists for these hazardous species is long and ever increasing. However, the photocatalysis method may come handy as a quick fix solution at industrial scale where degradation can be monitored visually by the change in color.

The rate of degradation (kinetics) is another area which needs serious attention for the purpose of defining authentic rate equations. Many previous reports have pointed out serious concerns over the use of L-H based models. The alternative ones are also under investigation and still not widely accepted as a universal model equation. At one end, while the revised rate equations need pragmatic assumptions to begin with; the final form of the equation should be more holistic to encompass all crucial variables, viz., synthesis parameters, reaction conditions etc. The approach towards photocatalysis for the degradation of dyes and pollutants hence need an out of box thinking for the solutions of novel and economic materials with innovative microstructure and properties; the process kinetics and scaling up issues (at industrial scale) need further monitoring for a benign solution.

For application purposes, one also needs to consider whether photocatalysis will be used as a stand-alone system or as a pre-treatment step and then further treated by other method (like physical or biological) for effective wastewater treatment. As photocatalysis requires continuous light irradiation for its operation, it would be advisable to use it as a pre-treatment step. It seems more logical to use it in combination with biological or physical method for its cost effectiveness and improved performance. In order to promote the feasibility of photocatalytic water treatment technology in the near future, several key technical constraints ranging from catalyst development to reactor design and process optimization have to be addressed. Some of these issues include its operating ability in the solar light, wide pH ranges for operation, minimizing the use of oxidant additives and sacrificial reagents etc.

Conclusion

Photocatalysis has the signature of a promising technology that has a number of applications in environmental systems such as air purification, water disinfection, hazardous waste remediation, and water purification. In addition, the basic research that underlies the application of this technology is promoting a new understanding of the complex heterogeneous photochemical process of metal oxide systems in different environments. The continuous exploration of new phases and materials as potentially improved photocatalysts will most likely provide exciting results in the coming years. However, a more integrated use of theoretical and advanced experimental techniques will be crucial for achieving a rapid and significant enhancement of the performance.

Giacomo Luigi Ciamician, a pioneering photochemist, presented his remarkable vision of “The Photochemistry of the Future” (Ciamician, 1912) at the International Congress of Applied Chemistry held in New York in 1912. He expressed his views that photochemistry, which was an entirely solar discipline at that time, could be an essential component of industry in the future: “On the arid lands there will spring up industrial colonies without smoke and without smokestacks; forests of glass tubes will extend over the plains, and glass buildings will rise everywhere; inside of these will take place the photochemical processes that hitherto have been the guarded secret of the plants, but that will have been mastered by human industry which will know how to make them even more abundant fruit than nature, for nature is not in a hurry and mankind is”.

Although solar photocatalysis has produced significant interest in research, it is still too young for commercialization: there are only a few examples of medium and large-scale solar photocatalytic chemical processes in industries around the globe. However, these few validate that solar photochemical production of selected fine chemicals and solar photocatalytic wastewater treatment (particularly for tropical regions), may be environmentally-benign alternatives to the existing traditional processes. The application of heterogeneous solar photocatalysis with TiO_2 (in particular) is expected to have a future beneficial impact on the environment, public health and society at large.

Finally, a particularly important long-term goal of visible-light photocatalysis will be the utilization of large-scale photochemical processes in commercial applications. The environmental benefits envisaged by Ciamician cannot be achieved if photochemical synthesis remains a largely academic assignment. Thus, the development of increasingly efficient, pragmatic and synthetically useful photocatalytic materials and their efficient degradation for the construction of fine and commodity chemicals should be an enduring goal for academic researchers and we anticipate that this will remain as an exhilarating task for many years to come.

Background of Literature Review on Wood-Waste Recycling

The broad objective of this review article is to present the published research findings on wood-waste recycling with aiming to support on going global sustainable development activities. This review has been designed for answering a few questions on problems relating to the effect of wood-waste recycling on mitigating climate change through reducing carbon emission, how timber industries meet required mechanical and chemical properties for achieving higher lifecycle of wood-waste based new materials. The other emerging issues this review article has addressed are the supply chain of collecting wood-waste, the major uses of wood-waste recycling, the contribution of engineering for developing new products from wood-waste, and the cost benefits analysis of wood-waste recycling. However, the total number of papers reviewed in this work is 139 and are all published in the year 1997–2018. The 10% of the papers outlined the potentials and the need for recycling of wood-waste. The uses and recycling of wood in building & construction, paper and furniture industries have been explained in more than 14% of the papers reviewed. The mechanical and chemical properties have been studied in 18% while in-depth analysis of the engineering contributions and its positive implication on the value chain of the recycled wood-waste has been analyzed in 25% of the papers reviewed. The remaining 33% of papers outlined the importance of wood recycling on the economic and environmental sustainability.

Historical evidence has shown that deforestation has been the primary source of raw materials for timber industries (Sun *et al.*, 2004; Köhl *et al.*, 2015). The raw wood supply to timber industries for producing building materials, furniture and other purpose has been formulating in line with the aim to achieve global economic growth (ISWA, 2010; Pirard *et al.*, 2016). A unit of United Nations (UN) subdivision: Food and Agriculture Organization (FAO) have made a forest Assessment Report (FAR) on forest resources, which indicated that wood-based manufactured products add more than \$450 billion to the world market economy annually (Köhl *et al.*, 2015; Moellendorf, 2015). This amount is equivalent to a total of 530.5 billion m^3 timber in 2015, and it has increased by 3.6 billion m^3 (0.7%) more than the total growth reported in 1990 (Gurnell, 2002; Ulubeyli *et al.*, 2017). However, this huge amount of wood sourcing from the forest is one of the main reason of deforestation and is responsible for about 20% of global carbon emissions (Gregory, 2008; Maratovich *et al.*, 2016), and it was 9Gt CO_2eq in 2017 (Yargicoglu *et al.*, 2015; EPA, 2017; Gregory, 2008; Maratovich *et al.*, 2016). In addition, there is a significant amount of carbon and CH_4 emit due to landfilling of wood-waste into the soil for decomposing in an anaerobic environment (Gregory, 2008). It has been stated that construction demolition waste alone generates an estimated 70.62 million metric tons of wood-waste material and disposable solid wood products per year in the united states (Falk and McKeever, 2004; Bratkovich *et al.*, 2014). However, the research published papers on wood-waste mainly focused on economic and engineering aspect in-line with sustainable development; but wood-waste recycling in-line with carbon emission linking with global warming potential (GWP) and climate change effect was not much; it indicates that a research gap exists in wood waste recycling domain. To fill up this gap, this study was designed for addressing all these mentioned issues. In that aspect, this review paper is novel as this work has addressed the contribution of wood-waste recycling to reduce carbon emission and GWP. Indeed, this review article has been written to provide adequate information on wood-waste processing for developing value-added new materials with higher lifecycle by improving required mechanical properties such as durability and modulus of elasticity. With this celebration, wood recycling article has been authored to provide data that will serve as a necessary guideline for future research in wood-waste management for contributing to achieving economic and environmental sustainability.

The Wood Waste Recycling Scenarios

Wood-waste can be regarded as a non-hazardous material that originates from household and commercial consumption of wood products such as furniture, demolition of buildings, refurbishment and renovation waste from construction sites, industrial packaging wood, and wood pallets (FWPA, 2008; EPA, 2014). The source of the wood-waste material is also very important as it

determines the processing method required to produce a value-added engineering material. It has been reported that wood-waste have a very diverse used in the economy for sustainable development activities. Indeed, the use of wood-wastes have been increasing in various uses because of its durability; and improvement in engineering design to make it environmentally friendly (Gurnell, 2002; Ulubeyli *et al.*, 2017). Some of the products that produce from wood-waste are animal bedding, equestrian surfaces, mulch, landscaping, as a bulking agent in composting and particleboard (Wilk *et al.*, 2010), and building materials. It must also be emphasized that different uses of wood-waste require the different level of purity and engineering properties that must take into consideration while designing new materials from wood waste (Yargicoglu *et al.*, 2015; EPA, 2017).

Global Wood Waste Recycling Scenario

The need for recycling wood-waste for producing new materials with required mechanical strength and higher lifecycle has become research interest area among engineers specialized in the field of material science (Defra, 2012). The commercial and research activities with wood-waste have focused into two streams; one is wood-waste from municipal solid wastes and another one is the demolition of old building (Defra, 2012). According to a study conducted by the Waste & Resources Action Programme (WRAP), some of the largest sources of wood-waste come from three areas (Defra, 2012).

(a) Municipal waste that consists of disposed items such as furniture, packaging and other wood related to waste from households. (b) Industrial and commercial waste that consists of wood waste come from wood products manufacturers and construction materials. (c) Construction and demolition waste that are made up of surplus structural timber unable to be used further, torn down structural wood and unwanted furniture from the demolition industry (Tolvic, 2011).

However, literature revealed a few ways of using wood-waste but the major ways are two. One way of using is recycling to produce new materials for building and manufacturing industries, and another way of using is to producing energy inline with the concept of waste to energy (WtE) (Clegg, 2017; Ramage *et al.*, 2017).

Recycled Waste-Wood for Energy and Fuel

The wood-waste which cannot be recycled in developing new materials are converting to energy in line with the concept of WtE (Clegg, 2017). Studies revealed that wood-waste are also used as a substitute for fossil fuels in the form of WtE (Rawat *et al.*, 2009; In-HO Choi *et al.*, 2013). In WtE process, wood-waste is used as boiler fuel for producing steam for turbine (Scotland, 2003; Shaw and Moore, 2011). It is reported that the wood-waste in the WtE application is positively associated with higher GHG emission and accounted for 55% higher than the burning of biogas for electricity production; in this aspect, wood-waste is not recommended for WtE (Clegg, 2017). It was also reported that between 2009 and 2013, there is the spontaneous increase of more than 20% wood-waste application in WtE and in globally this figure is quite higher. It is observed that the WtE application has been in use in European countries (EU) for electricity production (Canam and Campbell, 2009).

However, two categories of wood-wastes recommended for WtE: (1) Clean wood-wastes that are uncontaminated by harmful substances, and (2) wood waste contaminated with hazardous substances. Those uncontaminated are usually burn and used directly in power stations and private stoves, while those wood or chipboards containing adhesives and paints are used for WtE in specialized combustion equipment (Shaw and Moore, 2011).

A significant amount of Timber wastes are using in energy industries; for example, in the Netherlands, the huge amount of wood waste generated from C&D activities (Tam and Tam, 2006), most of these wood waste have used in power plants and hot water generation purpose.

It was reported that more than a million tons of Canadian waste wood pellets have been exported to the EU for using in power plant as substituted of fossil fuel (Northwoods *et al.*, 2008; European Commission, 2014; Edo *et al.*, 2016).

Recycled Wood Waste for Landfill

The last alternative at the end-of-life cycle scenario of wood-waste is the use as a landfill materials (Joely *et al.*, 2005). Landfill option is a costly practice compare to other available options as well. The practice of using wood waste for the landfill has been restricted in some part of Europe including Sweden, Austria, and Germany through the United Kingdom has allowed to a certain limit (Kale *et al.*, 2002). However, it has been reported that wood-waste containing some hazardous materials, which appeared as the main barrier to using wood waste for landfilling purpose (Shaw and Moore, 2011). It was reported that there are a few disadvantages associated with landfill, which are the slow biodegradation process that takes a longer time to decompose wood-waste. The lignin present in wood which is very resistant to decompose and this might take a very long period of time especially if the biodegradation is to take place in anaerobic conditions (Kale *et al.*, 2002). The wood waste also responsible for GHG emission which includes methane, nitrogen, and CO₂, (Kale *et al.*, 2002).

Recycled Wood Waste for Developing New Products

Development longer lifecycle materials from wood waste is a challenge due to composition of various quality of wood (Ramage *et al.*, 2017). The major challenge is the sorting of waste wood into different categories in order for the quality of the new materials.

The need to develop an efficient waste wood sorting is therefore very crucial to develop the quality product from the recycling process. The second step is pre-treatment for waste-wood prior to process for new material (Farsi, 2010). The third steps are selecting recycling process for developing new material as in this aspect process conditions, temperature, pressure and process duration are vital parameters. It has been reported that sorting process is not able to separate 100% impurities from wood waste, and a significant percent of other materials remain in the bulk wood waste such as metals and plastics that may affect the final product (Tsuchimoto *et al.*, 2016).

Recycling wood waste for developing building and construction materials

A large quantity of timber waste have been generated from construction and demolition works (C&DW). The United Kingdom produced more than 2.5 million tons of timber wastes each year (Tam and Tam, 2006). The reason for the higher quantity Timber in C&DW is of using these materials as a preferred quality structural material compares to concrete and steel (Forestry Commission, 2016). It has been reported that sawn wood waste is the major percent in C&DW (Chen, 2008).

However, the method of C&DW conversion to new materials is still new in the most of countries and even technology is costly. It is reported that 50%–95% of C&DW can be recycled for developing new value-added materials (Ulubeyli *et al.*, 2017). For example, Turkey established her first C&DW recycling industry in 2006 and this is continually been developed. Recently the EU (Directive 2008/98/EC) has set a target of recycling 70% C&DW materials in development activities (Ulubeyli *et al.*, 2017). The statistics of C&DW show that Netherland is successfully used 98.1%, Denmark 94.9%, Estonia 91.9%, Germany 86.3%, and Ireland 79.5%. Similarly, the U.S.A has achieved 73.5% of C&DW in recycling process.

Environmental benefits of recycling wood waste from construction and demolition waste

Today, the reduction of GHG emission has been achieved to a significant level through the recycling of C&DW (Ulubeyli *et al.*, 2017). A study jointly conducted by Columbia, British and Canada in 2017, the findings demonstrated that the use of wood-waste for developing new products is positively associated with mitigating climate change (Xu *et al.*, 2017). This study influenced several countries on data collection of wood waste (Werner *et al.*, 2010; Lundmark *et al.*, 2014; Nordström *et al.*, 2016; Russell and Kumar, 2017), and to investigate on the necessary parameters need to higher utilization of wood-waste for developing new products to mitigate climate change. The results obtained from various studies has been recommended for further applications on a global scale so as to exploit the potentials of C&DW that would contribute to restore the conservation forest resources through wood-waste management (Shahiduzzaman and Layton, 2015).

Recycling wood waste with concrete materials

It has been stated that structural efficiency of wood sometimes better than concrete and steel, though the structural efficiency of wood may reduce to a greater extent due to the unfavorable environment (Jeffrey, 2011). Based on this properties, wood waste chips mixed with cement has seen to increase the compressive strength of building materials. In an experiment, Thandavamoorthya (2015) found that 15% wood chips with 85% concrete produce higher strength cement, and its estimated value was about 32 Mpa; whereas cement produced from only concrete the compressive strength was only 25 Mpa. This experiment concluded that wood-waste could be a good choice in cement production (Thandavamoorthya, 2015). Mehmood stated that the hardwood is significantly stronger and can be used in some structure conveniently as a replacement of reinforced concretes (Mehmood *et al.*, 2010). Similarly, Timber has a higher stiffness than reinforced concrete, which makes it feasible to use as building materials (Oriyomi *et al.*, 2011). The low-density timber appeared a better choice for building due to its higher load-bearing strength, and higher strength-to-weight ratio. Sometimes timber is better building materials compare to concrete due to its higher elastic modulus-to-weight ratio. In all these aspects mentioned, wood-waste appeared a good option for converting it to building structural materials for increasing strength of building at a lower weight.

Recycling wood waste for developing industrial products

Wood waste from C&DW and furniture manufacturing can be reused after reprocessing through hydrolysis, gasification, pyrolysis, heat treatment, chipping and pulping process (Hendriks, 2000). After Cleaning, de-nailing and sizing, waste timber reused for making a plank, beam, door, floorboard, rafter, panel, balcony parapet and pile (Hendriks, 2000). In 2004, Japan developed a new technology in turning timber waste into furniture, wood bench, and timber stair (Tam and Tam, 2006). Wood waste from C&DW is also used to produce paper and recycled board. Clipped timber is recycled by spraying them onto sloped soil surface in Japan, which is called “fiber (Hiramatsu *et al.*, 2002)”. It has been reported that Japan developed a new technology to paving material timber chip, which is regarded as a high value-added product from waste (Tam and Tam, 2006).

Wood waste from C&DW is also recycled to develop building materials like wood-based panel for the roof, ceiling, floor, cladding, hoarding, as a packaging substitute and sound barrier for building (Tam and Tam, 2006). Woodchip of C&DW is also using to improve soil texture by mixing with topsoil. I has been reported that Timber waste is also used to produce insulation board, kitchen utensil and furniture (Sheidaei and Serwanja, 2016).

Recycling wood based waste furniture

Quality of new materials that produce from wood waste depends on from which quality of timber the original furniture was produced (Kaplinsky *et al.*, 2003). Australia is successfully utilizing her potentials in the recycling of furniture waste at a larger scale; it was reported that six companies currently in operation for recycling furniture wastes to produce various high-value-added

new products (Daian and Ozarska, 2009). The size of these companies is medium to large with yearly revenue about 7.3 million Euro per (Bruns, 2017). Different kinds of wastes used by these companies namely solid wood offcuts, sawdust, engineered wood offcuts and shavings (Bredemo and Mäkelä, 2008). They used both clean and contaminated furniture wastes for producing new products. The offcuts are usually clean and are free from contaminants such as dirt, chemical impurities, rock, and metal, while the mixture streams consist of shaving trims and sawdust (Liang *et al.*, 2012).

Different valued-added products are manufactured from waste timber including Veneers flakes, wood chips, and fibers (Mercer and Frostick, 2012). By using these waste wood elements, variety of building materials are produced such as plywood, laminated veneer lumber (LVL), glued laminated lumber, particleboard and medium density fibreboard (MDF) (Sinha and Miyamoto, 2014; Davids *et al.*, 2017).

Laminated veneer lumber from waste furniture

Laminated Veneer Lumber (LVL) has been producing from wood waste. The thickness of LVL product is from 2.5 to 4.8mm with significantly higher compressive and tensile strength (Book, 1997; Liang *et al.*, 2012). Studies show that the base wood of this product are pine, poplar, birch, or eucalyptus (Janowiak *et al.*, 2001; Kiliç, 2012). In product processing, the LVL fibers are arranged in a parallel way with the homogeneous mixture in order to increase its strength; and the strength-to-weight ratio (Ayrilmis *et al.*, 2009). The veneer is glued with melamine-formaldehyde and phenol-formaldehyde adhesives at required temperature and pressure in order to increase stability of product structure (Wang *et al.*, 2015; Sasaki and Abdullahi, 2016).

Parallel strand lumber from waste furniture

The Parallel Strand Lumber (PLS) is a building materials produces from different kinds of waste timber's chips, mostly pine, poplar, and Douglas. These strands are usually positioned in parallel length-wise manner (Clouston, 2007). PLS elements are about 3 mm thick, 20 mm wide, and 0.6–3.0 m long, and manufactured by cutting of the veneers (Hockey *et al.*, 2000). PLS is predominantly used as columns and beams, reaching up to 30 meters, as well as in frame construction (Donaldson, 2008; Huang *et al.*, 2012). Phenolresorcinol-formaldehyde glues adhesive are used to bond the strands together in order to increase its strength (Kurt *et al.*, 2013).

Laminated strand lumber from waste furniture

Laminated Strand Lumber (LSL) is a composite timber materials produced from waste furniture; and used in building structure (Mahdavi *et al.*, 2012). The production technology used to produce LSL is very similar to LVL, but the final product is thicker compared to LVL (Tannert and Lam, 2007). The standard size of strands are 0.8 mm thick, 20–50 mm wide, and 300 mm long. The strands are usually bonded at high pressure with polyurethane adhesives and steam (Nugroho and Ando, 2001). Initially, the strands are laid in parallel or crosswise before it cuts into desired and acceptable size. The orientation of the strands affects the strength of the material (Ma and Young, 2010). However, these strands are used as beams, rafters, or columns of a building. Sometimes it uses in building walls, ceilings, and floors (Çolak *et al.*, 2007; Ardalany *et al.*, 2010).

Research in Improving Chemical and Mechanical Properties of Wood Waste Based New Materials

A huge number of researches have been conducted on wood waste based materials to improve its mechanical properties, and to limit its recycling potentials (Hossain *et al.*, 2014). The major researches have been focused on various physical and chemical treatments, which contributed to prevent biological deterioration products and also improve its service life (Mohareb *et al.*, 2012).

Chemical Modification of Wood Waste Based Products for Improving Quality and Lifecycle

After chemical and heat treatment two types of inspection have been using; X-ray fluorescence (XRF) and laser-induced breakdown spectroscopy (LIBS) (Janin *et al.*, 2011). These characterization processes are capable of identifying two chemicals: chrome copper arsenate (CCA) and alkaline copper quat (ACQ). Both of them contain metals that contaminate recycled wood products (Conard Holton, 2001; Love, 2003; Yasuda *et al.*, 2006). The LIBS equipment is usually fixed in an air-conditioned room and connected by fiber optics to the wood waste recycling processing area. The LIBS laser beam is directly focussed on the shredded wood chips in order to identify chromium contamination (Rahman *et al.*, 2001).

There are various types of chemical modification process have been using in wood waste recycling process for improving mechanical properties of wood waste based products (de Guimarães *et al.*, 2015). Aside from the changes in mechanical properties, chemical modification process also used, which contribute to improve physical dimensions, increase resistance to fungi and moisture. The chemical modification of wood waste recycling process usually involved the adjustment of temperatures, the use of catalysts, water vapor, organic solvents and chemicals reactive (Bodirlau *et al.*, 2008). Therefore, the effect of chemical and heat treatment of wood is very important in determining the quality of new material (Epmeier *et al.*, 2004). The mechanical properties of the new products also determine whether it will be sustainable to use wood as an engineering material (Stoeckel *et al.*, 2013).

Table 1 Different mechanical properties of wood species before and after heat treatments

Wood species	Media	Moisture Content		Changes in mechanical properties Static bending (Fresh)		Changes in mechanical properties Static bending (Recycled)	
		Fresh	Recycle	MOE	MOR	MOE	MOR
Softwood	–	12.2	5.3	–	– 15	–	4.0
Hardwood	–	10.5	6	–	– 20	–	3
Pine 1	Air	0	0	– 32	– 33	0	0
Pine 2	Steam	12.6	4.5	– 40	– 5	0	–
Beach	Gas	11.3	4.9	11	– 26	10	–

Heat Treatment of Wood Waste Based Products for Improving Quality and Life Cycle

Heat treatment of wood is usually conducted within the ranges of 150–230°C in a shield media such as steam, nitrogen gas, vegetable oils or under a vacuum; and it would apply for both fresh wood and recycle wood processing (Martin *et al.*, 2013). The report of various studies demonstrated that heat treatment had played a vital role in improving mechanical properties of materials developed from waste wood. Indeed, heat treatment is also contributed to reducing hydrophobicity and greater dimension stability (Tascioglu *et al.*, 2003; Service, 2010). The mechanical properties modulus of elasticity (MOE) and the modulus of rupture (MOR) of wood are highly affected by heat treatment, but the effect of heat on MOE and MOR is less effective on wood products developed from wood waste (Tiryaki and Hamzaçebi, 2014). This scenario is presented in Table 1.

The effect of heat treatment on mechanical properties is significantly good as stated by Hein *et al.* (2013); he demonstrated from his study results that load-deflection properties had appeared better for wood-waste based new materials compare to fresh wood (Hein *et al.*, 2013). The general effect of the different kinds of media on the mechanical properties of a different kind of fresh and recycled wood after heat treatment represented in Table 1 Hein *et al.*, 2013; Tiryaki and Ha. For example, Beach wood treated at 220°C for 4 h in Gas media exhibited an improvement of approximately 11% in MOE but a reduction of more than 26% in MOR when tested after conditioning at 20°C.

Improvement Mechanical Properties in Wood Waste Based New Materials

The mechanical properties of timber are the determinants of using this material in construction industry. The required properties that consider are bending strength (σ_b ; Pa), bending stiffness (MOE, modulus of elasticity; Pa) compression strength (σ_a ; Pa) and compression stiffness (E, Young's modulus; Pa) (Xie *et al.*, 2013). However, mechanical properties improvement of new materials made from wood waste would be enhanced by chemical and heat treatment (Service, 2010). In chemical modifications process, solvents, organic compounds, water vapor and reactive chemicals are extensively used. It has also been reported that Acetylation, Furfurylation, Resignation, Wax treatment, and Grafting methods are the proven ways that have been used in wood treatment for improving mechanical properties (Belgacem and Gandini, 2008).

Mechanical properties improvement by using waxing method

The treatment by waxing has been established to increase mechanical properties of wood. It has been reported that MOR, MOE, and bending strength of wood waste materials can be increased up to 25%, 11%, and 31% respectively by Using Waxing Method (Scholz *et al.*, 2012).

Mechanical properties improvement by using grafting method

Grafting modification process, Vinyl Monomers is used. It has been reported that the treatment sugar maple wood with vinyl monomers has increased MOE and MOR by 20.0% and 28.0% respectively (Rowell, 2012). This process is also contributed to increase tensile strength and compression strength in wood waste based new materials (Scholz *et al.*, 2012).

Mechanical properties improvement by using furfurylation method

The chemical modification of wood product by using Furfurylation is positively associated with mechanical properties. It has been reported that while pine species sap wood treated with Furfuryl alcohol (FA) contributed to increase MOR and MOE by 6% and 38% respectively (Esteves *et al.*, 2011). In addition, the chemical modification of wood by using FA also contributed to improving dimensional stability, reduced water uptake capacity, and increase resistance to biological deterioration.

A Short Inventory on Research for Improving Wood Waste Recycling Performance

A large number of engineers have intensified their researches for optimizing wood-waste recycling in producing higher value-added materials for the economy (Sui and Chen, 2014). It has been suggested that to improve mechanical behavior of waste

timber-based products, need for an in-depth study on basic parameters such as physical, mechanical and chemical characteristics of wood waste-based materials (Donaldson, 2008). Inputs from engineering to recycling of wood-waste processes is essential for improving the quality of products as well as process performance. It has been reported that to achieve desired quality products from wood waste, process parameters namely compression time, temperature and pressure need to control precisely; in this aspect, R&D is essential (Hiramatsu *et al.*, 2002; Stelte, 2013).

Other aspects of researchers that getting attention and have been well documented in the published literature are the enhancement of mechanical properties including improvement of the strength and stiffness (Burgert *et al.*, 2002). In various studies, a few indicators have used to evaluate the properties of products developed from wood waste. The indicators are Knots, annual ring width, modulus of elasticity (MOE) and density of timber (Institute, 2005; Tabet and AbdulAziz, 2013).

For enhancing research towards improving mechanical properties of wood waste-based materials, Cave (1997) suggested that the coefficient of quality determinant could be compared with the mechanical properties indicators as independent variables (such as knot, annual ring width, density, and MOE) and tensile and bending strength could be the dependent variable (Cave, 1997; Huang *et al.*, 2012; Toolbox.com, 2015).

Effects of Recycling Wood-Waste on Environmental Sustainability

The estimated carbon density in the air was 405 ppm as of 2017. In future, it would be 450 ppm in 2050, and 750 ppm in 2100 (IPCC, 2017). It has also been reported that the Global carbon was 45GtCO₂ in 2017. Various studies reports demonstrated that about 20% of this carbon is emitted from deforestation process, while wood collect from the forest. It is saying that wood waste recycling will definitely contribute to reduce deforestation and reduce GHG emission (Nzeadibe, 2009; Song and Li, 2014). It has been reported that recycling wood waste for developing new materials will contribute to conserving natural resources (Nzeadibe, 2009; Yau, 2012). With the development of a market for wood-waste, overall health of the forests would improve (Song and Li, 2014). It has been reported that the efficient use of wood waste has a multiplier effect on the conservation of forest resources with a very appreciable reduction in GHG emissions and biodiversity loss (Spittlehouse and Stewart, 2003).

Recycling Wood Waste for Saving Carbon Sink

Forest is proven carbon sink, which could be saved by efficient utilization of wood-waste is to contribute to reducing deforestation, carbon emission by protecting carbon sink (Huron *et al.*, 2017). In this concern, Tsunetsugu and Tonosaki, (2017) reported that the utilization of wood-waste in the construction industry would contribute to reducing a significant amount of GHG emission due to saving carbon sink deforestation. It was also reported that this kind of wood-waste utilization for construction purposes and other uses would definitely reduce climate change due to reducing of GHG emission (Soimakallio *et al.*, 2016; Wang and Chen, 2016).

Economy of Waste Wood Recycling

It has been reported that wood-waste recycling for producing new products is an economically viable project because it conserving natural resources (Laurijssen *et al.*, 2010; Carpio *et al.*, 2013). Recycling of wood-waste has been regarded as a source of renewable material supply for economic development (Greyson, 2007). The indirect contribution of Wood Waste recycling is to establish supply chain network for collecting wood waste which would enhance economic growth and create employment opportunity (Björklund and Finnveden, 2005). The wood-waste recycling effort has also guaranteed the continued sustainability of the forest reserve in the emerging economies (Chen *et al.*, 2012; Bergeron, 2014). Wood brings ecological balance in the environment, which has a wider economic benefit in terms of achieving higher agriculture productivity. In the report, Ramage *et al.* (2017) stated that the utilization of wood-waste in the construction industry would be contributed to increase various activities, which would be enhanced the growth of local economy (Ramage *et al.*, 2017).

Supply Chain and Economic Benefits for Wood Waste Recycling

The degree of supply chain strength for collecting, transporting and processing has a positive effect on wood waste recycling performance (Kassim and Ali, 2006; Das and Bhattacharyya, 2015). In a study, Asif (2009) found that reuse of wood-waste in developing new materials and other economic use depends on the cost-effectiveness of wood waste collection (Asif, 2009).

It has been reported that the volume-based fee for disposal system has appeared an effective method for promoting wood-waste recycling (Hong, 1999; Lee and Paik, 2011). It has been observed that the quantity of wood-waste recycling has increased significantly as people are asked to pay for disposing of their waste (Wath *et al.*, 2010). It has been also reported that the amount of wood-waste collection from apartments is higher compared to detached single houses due to the availability of strong supply chain system (Tan and Tracey, 2007).

The existence of recycling bins close to residences and the availability of waste management staff has also contributed to the increasing wood waste supply chain network. However, wood waste recycling performance depends on a few factors such as the availability of lobby for collection, specific space in community for disposing off waste wood; affordable technology for converting

waste to value-added materials, and finally government support for establishing strong supply chain net (United Nations, 2011; Australian Government, 2012).

The immediate benefits of recycling wood waste are the avoidance of landfill cost and saving of space costs (Atkinson and Mourato, 2008). In an estimate Merry *et al.* (2009) has shown that benefits cost ratio of wood waste recycling is more than one, which indicate that wood waste shall recycle project is economically feasible (Merry *et al.*, 2009).

Conclusion

This review presents the research outcomes published in various scientific journals on wood-waste recycling. This paper outlined the potentials of wood waste recycling in developing new materials to be used in building & construction, paper and furniture industries. This review listed the research outcomes published relating to mechanical and chemical properties of wood waste based materials, which revealed that wood waste recycling for developing new materials would contribute to reduce deforestation and carbon emission. This paper discussed the major challenges and opportunities of wood waste recycling industries; and contributions of engineering to address the challenges. Lastly, this review disclosed that wood waste recycling is positively associated with reduction of global carbon reduction and climate change. This review concludes that engineers and scientist shall conduct further R&D on wood waste value chain for increase recycling performance for achieving sustainable development through economic and environmental sustainability.

Water Resource Management for Renewable and Sustainable Hydro Energy in Turkey

Ibrahim Yuksel, Yildiz Technical University, Istanbul, Turkey

© 2020 Elsevier Inc. All rights reserved.

Introduction

Because of social and economic development, the demand for energy and particularly for electricity is growing rapidly in Turkey. The main indigenous energy resources are hydro and lignite. Turkey has no big oil and gas reserves but it has a large potential for renewable energies. Turkey's geographic location has several advantages for extensive use of most of the renewable energy sources. It is on the humid and warm climatic belt, which includes most of Europe, the near East and western Asia (Yuksel *et al.*, 2005; Paish, 2002).

Owing to Turkey's regions, most of which are hilly, it is possible to develop relatively higher heads without expensive civil engineering works, so relatively smaller flows are required to develop the desired power. In these cases, it may be possible to construct a relatively simple diversion structure and to obtain the highest drop by diverting flows at the top of a waterfall. There are intensive investigations to improve small and large hydropower development in Turkey and some small hydropower plants are still under construction.

The development of hydro-electricity in the 20th century is usually associated with the building of large dams. Hundreds of massive barriers of concrete, rock and earth were placed across river valleys world-wide to create huge artificial lakes. While they created a major, reliable power supply, plus irrigation and flood control benefits, the dams necessarily flooded large areas of fertile land and displaced many thousands of local inhabitants. In many cases, rapid silting up of the dam has since reduced its productivity and lifetime. There are also numerous environmental problems that can result from such major interference with river flows (Yuksel *et al.*, 2016).

Small, mini and micro hydro plants (usually defined as plants less than 10 MW, 2 MW and 100 kW, respectively) play a key role in many countries for rural electrification. Small-scale hydro is mainly 'run of river,' so does not involve the construction of large dams and reservoirs. Small hydro currently contributes over 40 GW of world capacity. The global small hydro potential is believed to be in excess of 100 GW. The industry believes that small hydro will have a strong resurgence in Europe in the next 10 years, after 20 years of decline (Yuksel *et al.*, 2016).

Turkey's energy demand is met through thermal power plant consuming coal, gas, fuel oil and geothermal energy, wind energy and hydropower. Because Turkey does not own any nuclear power plant yet, the installation of the first nuclear power plant with a capacity of 1000 MW is on the schedule as a plan for the near future. In 2008, the energy consumption of Turkey was about 106,525 kilo tons of oil equivalent (ktoe) as shown in Table 1 (DPT, 2010).

Turkey's installed generation capacity is also 41.818 GW and electricity generation is 198.418 GWh in 2008. According to Turkey's Ninth Plan, 66% of Turkey's generated electricity is supplied from thermal power plants. Contribution of wind and hydro power plants are 0.2% and 32.20%, respectively. 49% of Turkey's electricity is generated by Electricity Generation Incorporation (EUAS), 39.70% is generated by auto-producers, and 9.5% is generated by affiliated partnerships of EUAS and 1.8% by distribution of electricity generation by primary resources by 2007 is given in Fig. 1 (DPT, 2010; TEIAS, 2007; Yuksel, 2015; DSI, 2010; MENR, 2008; WECTNC, 2008; EIE, General; RTLED, 2004; Yuksel, 2012).

Table 1 Primary energy consumption (ktoe)

Energy sources	2008	2009	2010
Hard coal	16,427	16,165	16,861
Lignite	15,217	15,031	15,891
Petroleum products	31,784	27,652	29,312

Fig. 2 Annual water budget in Turkey. Reproduced from DSI, 2009. State hydraulic works. Turkey Water Report. Ankara, Turkey.

Water Budget and Consumption

There are 25 hydrological basins in Turkey. The rivers in these basins often have irregular regimes. The basins have a total surface water run-off of 193 billion $\text{m}^3 \text{ year}^{-1}$ 31% of the potential is constituted by the Euphrates (Fırat) and the Tigris (Dicle) Rivers both of which have their sources in the eastern part of the country. Fig. 2 shows, annual water budget, Tables 2 and 3 show domestic and industrial water use in Turkey respectively (DSI, 2009).

Energy Situation in Turkey

A demand prediction model, called “Model for Assessment of Energy Demand” (MAED) was used to predict Turkey’s long term electric energy demand. This model, prepared by International Atom Energy Agency (IAEA), is a simulation model which evaluate mid and long term energy demands. MAED evaluates future energy needs based on medium to long term scenarios of socio-economic, technological and demographic development in a country or region.

The electric energy demand varies according to various parameters. The main parameters to affect the energy demand are: Gross National Product (GNP); population and demographic variations; development in housing, industry, agriculture and transportation sectors; income per capita; climatic conditions; employment, technological development, etc. Three kinds of planning scenario were applied in the model and MAED Model was executed for three scenarios and Turkey’s annual electric energy demand values were predicted from 2004 to 2020. According to the results of the study, Turkey’s annual electric energy demand in 2020 is predicted between 407 and 571 TWh (Paish, 2002; Kaygusuz, 2009).

For any analysis of the future demand for energy in Turkey to be accurate, it has to be grounded in the understanding that rapid and continued economic growth are and will remain the single most important national aspirations. According to 2005 figures,

Mtoe, Million ton oil equivalent; KEP, Kilogram of oil equivalent.

TUBITAK, 2003. Turkish scientific and technical research council. In: Proceedings of the Vision 2023 Technology Project: Energy and Natural Resources Panel, Ankara, Turkey.

Turkey has a population of 72.6 million. This translates to a per capita GNP of \$4900 and per capita energy consumption of 1.2 million ton oil equivalent (Mtoe), placing Turkey last in both categories among OECD countries (Yuksel, 2010). The projection of Turkey's population, economy, and energy is given in the Table 4 (TUBITAK, 2003). It is worth emphasizing that, even if both population and economic output were to grow more slowly than projected, it is almost certain that energy demand will increase.

Two factors critical to sustainable energy development in Turkey, however, are harder to predict. The first is the energy intensity of the economy. While the reported and predicted decreases seem impressive, it is by no means clear from this table whether this is the best that can be achieved in Turkey. If even sharper reductions are possible, increased economic growth could be delinked from energy consumption. The second is the type of primary and secondary energy sources that are required to fulfill future energy needs.

In other words, the decision on the mix of energy production technologies and primary sources needs to be considered carefully, as certain combinations of technologies and primary sources are likely to result in more sustainable outcomes. It is important, therefore, to understand the determinants of energy intensity and energy supply (Yuksel, 2010).

In Turkey, energy intensity has been relatively steady for the last two decades. Total final consumption (TFC) was 64 Mtoe in 2003, up by 54% from the 1990 level. In 2003, oil accounted for 41% of TFC, electricity 15%, coal 21%, combustible renewables and wastes 9%, natural gas 12%, geothermal 1.2% and solar and wind 0.5%. The share of oil and the combustible renewables and waste (largely non-commercial energies) has declined since 1990 whereas the use of gas, electricity and to a smaller extent coal has increased (IEA, 2005).

The structure of industry in Turkey is energy-intensive. The iron and steel sector is the biggest energy consumer among the industrial sectors (3.3 Mtoe in 2003), textile and leather industries (1.5 Mtoe) and chemicals and petrochemicals (2.2 Mtoe excluding feedstock); the cement industry is also among the largest industrial energy consumers. Industrial energy consumption (including non-energy use) more than doubled between 1990 and 2003 reaching 29 Mtoe. Industrial production grew over the same period by 49.5%. The government estimates that industrial energy consumption will increase by 53% from 2003 to 2010. The sector consumes large amounts of coal (39.5% of sectoral demand) and oil (29.6%) followed by electricity (15.4%), gas (15.1%) and other fuels (0.4%) (IEA, 2005). Energy consumption in the transport sector grew by 29% between 1990 and 2003, reaching 12.4 Mtoe. For the period from 2003 to 2010, the government expects a 61% increase in energy use in this sector. There

Fig. 3 Between 1973 and 2020, total primary energy supply in Turkey. Reproduced from IEA, 2005. International energy agency. In: Proceedings of the Energy Policies of IEA Countries: Turkey 2005 Review, Paris, France: IEA. *Includes geothermal, solar, wind, combustible renewables and waste.

Fig. 4 Between 1973 and 2020, energy production by sources in Turkey. Reproduced from IEA, 2005. International energy agency. are about 67 cars per 1000 inhabitants in Turkey but regional variations are large; whereas, for example, in the Marmara Region the car density is 90 per 1000 people, in Eastern and South-Eastern Anatolia the density is only 20 per 1000 people. Road has been the dominant means of transport for decades; during 1996–2000 about 96% of passenger transport occurred on roads. The share of road in freight transport is about 90% and rail 5%. Freight transport volumes have been increasing by almost 8% per year. Detailed statistics and trends for the number of vehicles, mileage and the share of different modes of transport are not available because statistics in the transport sector are not carried out regularly. The last statistics on the transport sector were issued in 1998 but the quality was so poor that they were not published (IEA, 2005).

Along with the economic growth and population increase, significant increases were observed both in primary energy and electricity consumption during the 8th Plan period (DPT, 2010; Yuksel, 2009). Consumption of primary energy reached 94.3 Mtoe as of the end of 2005 with an annual average increase of 2.8% while electricity consumption reached 165.3 billion kWh with an annual average increase of 4.6% during this period. These increases are more evident in the period following 2003, since the impact of the 2001 economic crisis was alleviated, and the economy stabilized. Between 1973–2020, Figs. 3, 4 and 5 show total primary energy supply, energy production, final energy consumption in Turkey respectively (IEA, 2005).

As a Renewable Energy Hydropower

Hydropower is the largest renewable resource used for electricity. It plays an essential role in many regions of the world with more than 150 countries generating hydroelectric power. About 10 countries obtain essentially all their commercial electricity

Fig. 5 Between 1973 and 2020 total final energy consumption in Turkey. Reproduced from IEA, 2005. International energy agency. In: Proceedings of the Energy Policies of IEA Countries: Turkey 2005 Review, Paris, France: IEA.

from hydro, including Norway, several African nations, Bhutan and Paraguay. There is about 700 GW of hydro capacity in operation worldwide, generating 2600 TWh year⁻¹ (about 19% of the world's electricity production). About half of this capacity and generation is in Europe and North America with Europe the largest at 32% of total hydro use and North America at 23% of the total. However, this proportion is declining as Asia and Latin America commission large amounts of new hydro capacity (Herzog *et al.*, 2012).

In the last decades, hydropower continues to be the most efficient way to generate electricity. Modern hydro turbines can convert as much as 90% of the available energy into electricity. The best fossil fuel plants are only about 50% efficient. In the U.S., hydropower is produced for an average of 0.7 cents kWh⁻¹. This is about one-third the cost of using fossil fuel or nuclear and one-sixth the cost of using natural gas. Hydro resources are also widely distributed compared with fossil and nuclear fuels and can help provide energy independence for countries without fossil fuel resources.

There is also significant, widespread activity in developing small, mini and micro hydro plants. At least forty countries, particularly in Asia and Europe, have plants under construction and even more have plants planned. China, Brazil, Canada, Turkey, Italy, Japan and Spain all have plans for more than 100 MW of new capacity (Herzog *et al.*, 2012).

It is well known that the hydropower industry is closely linked to both water management and renewable energy production, and so has a unique role to play in contributing to sustainable development in a world where billions of people lack access to safe drinking water and adequate energy supplies. On the other hand, approximately 1.6 billion people have no access to electricity and about 1.1 billion are without an adequate water supply.

However, resources for hydropower development are widely spread around the world. Potential exists in about 150 countries, and about 70% of the economically feasible potential remains to be developed – Mostly in developing countries where the needs are most urgent (EIA, 2006; AR American Rivers, 2004). Fig. 6 shows the estimated hydropower development by region in the world (IHA, 2003).

Water Management for Renewable and Sustainable Energy in Turkey

The role of energy utilities to deliver energy savings should not be underestimated in Turkey-planned measures to allow energy efficiency measures to be bid into energy pools on an equal basis to energy supply options should be implemented, or other relevant policy measures should be considered.

Although Turkey has an adequate amount of water in general, it is not always in the right place at the right time to meet present and anticipated needs. As regards hydrology, Turkey is divided into 26 drainage basins. The rivers in general have irregular regimes, and natural flows cannot be taken directly as usable resources. The average annual precipitation, evaporation and surface runoff geographically vary greatly (DPT, 2010; Yuksel, 2015, 2008a; DIE, 2004; DSI, 2004; MENR, 2005).

Turkey has 665,000 ha of inland waters, excluding rivers and small streams. There are 200 natural lakes, with a total area of 500,000 ha, and 775 dam lakes and ponds with a total surface area of 165,000 ha (DPT, 2010; Yuksel, 2015; DIE, 2004). With the projects developed primarily by DSI and other institutions engaged in water resources development, water consumption in Turkey reached 39.3 billion m³ by 2000, corresponding to only 36% of the economically exploitable water resources.

During water consumption estimates on a sectoral basis, it is accepted that all of the economically irrigable land will be irrigated with irrigation schemes constructed by the year 2030 and water consumption for irrigation will be 71.5 billion m³. Hence, while its share in the total consumption was 75% in 1999, the share of irrigation water in the total water consumption will be decreased to 65% by the year 2030, through the utilization of modern irrigation techniques (DPT, 2010; Yuksel, 2015; MENR, 2005; Ozturk *et al.*, 2009).

Fig. 6 Estimated hydropower development by region in the world. Reproduced from IHA, 2003. International Hydropower Association. In: Proceedings of the Role of Hydropower in Sustainable Development, pp. 1–140. IHA White Paper.

According to Chambers of Turkish Electrical Engineers, Turkey has 259 billion kWh energy potential, but only 35% of this potential can be used. Nowadays, Turkey's electricity generation is approximately 176 billion kWh per year and will be 400–500 billion kWh per year by year 2020. Turkey does not have enough primary energy sources, but has a tremendous hydropower potential.

Nowadays, hydropower is recognized as the most important kind of renewable and sustainable energy sources. The position of hydro power plants (HPP) becomes more and more important in today's global renewable technologies. The small-scale renewable and distributed generation may be the most cost-effective way to bring electricity to remote villages that are not near transmission lines (DPT, 2010; Yuksel, 2015; DSI, 2010, 2009; Alboyaci and Dursun, 2008). In terms of hydropower potential, with 440 TWh year⁻¹, Turkey is the second richest country after Norway in Europe. This potential can be used technically 215 TWh year⁻¹ and economical potential 128 TWh year⁻¹ in accordance with the predictions of General Directorate State Hydraulic Works (DSI). Table 5 shows the status of economically feasible hydropower potential in Turkey (DSI, 2009).

GAP Factor on Hydro Energy for Renewable Energy in Turkey

Water and hydropower potential in Turkey are distributed into 26 basins and the total flow rate of water sources for energy production is 186 km³ years⁻¹. The biggest five basins of Turkey are Euphrates, Tigris, Eastern Black Sea, Coruh and Seyhan as shown in the Fig. 7 (DSI, 2006).

On the other hand, 27 billion kWh of electricity will be generated annually over an established capacity of 7460 MW. The area to be irrigated accounts for 19% of all the economically irrigable area in Turkey (8.5 million hectares), and the annual electricity generated will account for 22% of the country's economically viable hydroelectric power potential, 118 billion kW by 2006. At the present the Ataturk and Karakaya dams, the most important investments of the GAP, had generated about 175 billion kWh energy. Table 6 shows the energy production in GAP (Southeastern Anatolia Project GAP, 2004).

Turkey has made some progress in implementing energy efficiency policies since the 2009 Evaluation. In the industrial sector, for example, between 2009 and 2010, Turkey trained and certified 1525 energy managers. The total number of certified energy managers in Turkey reached more than 4200 in mid-2011. It also hosted the 9th international energy manager course in June 2010. Measures and voluntary agreements, begun in 2009, to encourage energy efficiency in industrial establishments were continuing in 2010 (DPT, 2010; DSI, 2010; Kavak-Akpinar and Akpinar, 2004).

Turkey is attempting to improve methods to ensure both voluntary and mandatory energy efficiency policies are adequately monitored, enforced and evaluated. For example, a new Division of Monitoring and Evaluation was established in the General Directorate of Electrical Power Resources Survey Administration (EİE) at the end of 2010. A new project is planned for 2011 to establish a comprehensive monitoring and evaluation system and infrastructure (DPT, 2010; DSI, 2010; Kavak-Akpinar and Akpinar, 2004).

On the other hand, the second prong of the criticisms launched by the Greens is that Turkey has abundant potential for alternative energy sources. Recently, a spate of studies by Turkish scientists has demonstrated that significant unexplored renewable energy potential exists in wind, biomass, geothermal, and solar (Kavak-Akpinar and Akpinar, 2004; Kaygusuz and Turker, 2002;

Table 5 The status of economically feasible hydropower potential in Turkey

Project	Number of project	Total installed capacity (MW)	Annual average energy (TWh year ⁻¹)	Ratio (%)
In operation	172	13,700	48	35
Under construction	148	8600	20	14
In program	1,418	22,700	72	51
Total	1,738	45,000	140	100

Table 6 Energy production in GAP

Name of dam	Yearly energy production (kWh)
Karakaya dam and HPP	106.8 billion
Ataturk dam and HPP	74.5 billion
Kralkızı dam and HPP	0.3 billion
Karkamış dam and HPP	0.6 billion
Dicle dam and HPP	0.1 billion
Birecik dam and HPP	1.6 billion
Total	183.9 billion

Note: Southeastern Anatolia Project (GAP), 2004. Energy and water in the GAP region. Available from: <http://www.gap.gov.tr>.

Kose, 2005; Oğulata and Oğulata, 2002; Kaygusuz, 2002). These alternative energy sources support the general tendency of the Greens to favor small-scale and alternative technologies.

These studies make it clear that, especially when combined with efficiency gains, renewable energy sources stand to meet a significant proportion of the future energy need of Turkey (Yuksel *et al.*, 2005; TUBITAK, 2003; Yuksel, 2006; Kaygusuz and Kaygusuz, 2004; Evrendilek and Ertekin, 2003; Balat, 2004; Hepbasli and Ozgener, 2004; Yuksek and Ucuncu, 1999). **Table 7** shows the energy potential of the Southeastern Anatolia Project (GAP), in Turkey (DSI, 2009).

In Turkey, the hydropower industry is closely linked to both water management and renewable energy production and thus has an important role, in cooperation with the international community, and in striving for sustainable development in a world where billions of people still lack access to safe drinking water and adequate energy supplies.

The Role of Small Hydropower on Energy Demand

At the beginning of 2000s, the Turkish government began privatizing some of its electricity generating and distribution networks, and allowing for more private construction and ownership in the sector. The annual average precipitation in Turkey is nearly 643 mm, corresponding to a volume of 500 km³. The average runoff coefficient is 0.37, and the annual runoff is 186 km³ (2400 m³ ha⁻¹).

Table 7 The energy potential of the GAP

	<i>Installed capacity (MW year⁻¹)</i>	<i>Generation (GW year⁻¹)</i>	<i>Capacity project value (Million \$)</i>
In operation	4,214	16.296	4,779

Euphrates basin	874	3.068	1,656
Tigris basin	1,170	6.317	2,803
Total	7,490	27.384	10,650

Note: DSI, 2009. State hydraulic works. Turkey Water Report. Ankara, Turkey.

Subtracting from this figure the estimated water rights of neighboring countries, minimum stream flow requirements for pollution control, aquatic life and navigation, and topographic and geologic constraints; bringing the total consumable potential to 107 km³ (Bakir, 2005). Taking into consideration the electric energy demand predictions and the hydropower potential according to the new criteria, it can be easily predicted that, Turkey's hydropower potential can meet nearly 33%–46% of its electric energy demand in 2020, depending on the energy demand scenario.

Moreover, in these calculations, many of small hydro power (SHP) plants are not taken into consideration. By evaluating these resources, of which potential may be in the order of some tens of TWh year⁻¹, it is obvious that, Turkey will provide important part of its electric energy demand from its own hydro power resources. The findings of two case projects strongly support this opinion. SHP is especially very important in the Eastern Black Sea Region, which has abundant SHP capacity due to its meteorological and topographic properties, and this potential can be easily and economically developed. By doing this, the economical status of the rural people, most of whom are unemployed and poor, will be significantly improved.

According to findings of a study carried out (Bakir, 2005), in which a new criterion was developed related to key concept of “the economical feasibility”, by taking into consideration some undervalued benefits of hydro plants and some overvalued benefits of thermal power plants; economically feasible hydropower potential goes up 188 TWh year⁻¹, with an increase ratio of 47% compared to DSI value.

Prices and Competition on Energy Sector in Turkey

Retail electricity prices are relatively high in Turkey, at approximately USD 0.163 kWh⁻¹ for households and USD 0.1 kWh⁻¹ for industrial consumers. Turkey currently has implicit cross-subsidies between regions and for certain subcategories of consumers. The government is considering a transition period, with a tariff equalization method, to reduce cross-subsidies and progressively introduce cost-effective tariffs in the medium term. Differences in energy prices are mainly due to tax differentiation by fuel types: The special consumption tax on natural gas is much lower than on fuel oils. However, no special consumption tax is applied to coal (DSI, 2006).

The development of nominal electricity prices for industrial and residential customers over the last two decades in US cents per kWh, respectively. Note that following rapid increases between 1985 and 1993, prices have fallen again. This is partly because of insufficient inflation adjustment and falling real prices. Note also that prices for industrial consumers are almost exactly as high as for residential consumers.

Turkish Electricity Generation-Transmission Corporation (TEAS) publishes its end-1999 direct sales prices per kWh for industrial customers as US cents 6.87 for high-voltage customers and US cents 7.15 for intermediate and low-voltage customers, whereas its sales prices to distributors are in the range of US cents 4 per kWh and sales prices to Turkish Electricity Distribution Corporation (TEDAS) are around US cents 3.5 per kWh (IEA, 2001).

However, the gap between cost and prices is likely to be much larger than suggested by these data. Whereas TEAS states that its average net generating costs are as indicated in Table 6, the cost of purchasing additional electricity from build-own-transfer (BOT), build-own-operate (BOO) and Transfer of Operating Right (TOOR) generators (see below) is much higher (except for diesel peaking plants), and can reach US cents 11–12 per kWh. Since these plants are urgently needed because of the lack of supply capacity, and are therefore dispatched frequently, TEAS's full costs are likely to be significantly higher than the average cost listed in Table 8 (IEA, 2001).

As a consequence, TEAS's income statements have long shown significant losses; in 1999, losses amounted to more than 61 billion Turkish lira. These losses are eventually borne by TEAS's shareholder, the Republic of Turkey, thus contributing to the government budget deficit and, eventually, to inflation. The developments described so far were superseded by the adoption of the new Electricity Market act on 20 February 2001 by the Turkish Grand National Assembly. This Act fundamentally changes the structure of the Turkish power industry and ends the use of BOT and TOOR schemes in Turkey. The Electricity Market Act of 2001 is to come into force in early 2003, following a two-year transition period. It aims at creating a competitive, transparent and financially strong electricity market that encourages private investment without government guarantees, provides sufficient,

Note: IEA, 2001. International Energy Agency. In: Proceedings of the Energy Policies of IEA Countries Review, Paris, France: IEA.

Fig. 8 Between 1973 and 2020, Electricity of Generation by sectors in Turkey. Reproduced from IEA, 2005. International Energy Agency. In: Proceedings of the Energy Policies of IEA Countries: Turkey 2005 Review, Paris, France: IEA. *Includes geothermal, solar, wind, combustible renewables and waste.

reliable and low-cost electricity to consumers and is compatible with the European Union Electricity Directive. Between 1973 and 2020, **Figs. 8** and **9** show electricity of generation and final conception by sectors in Turkey respectively (IEA, 2005).

A competitive electricity market is to be established, based on bilateral contracts between market participants. Within two years of entry into force of the act, i.e., in March 2003, customers consuming more than 9 GWh will be eligible for competition. A short-term market will be created to allow system balancing. If market conditions permit, distribution and retailing activities will be separated. TEAS will be divided into three different companies: A generation company, an independent transmission operator, and a wholesale trading company. The establishment of the three companies had already been provided for by Decree No. 310 of 3 March 2000 and will now be put into effect. The electricity generation company is to retain all power plants not yet transferred from TEAS via the TOOR procedure. It will also operate the nuclear power plants that the government still expects to come on stream by 2008, as well as "strategic" power plants (IEA, 2001).

The transmission company will be responsible for transmission and nondiscriminatory dispatch of all power plants. The wholesale trading company is to be responsible for buying and selling electricity at wholesale level. It will succeed TEAS in the power purchase agreements concluded with the BOT and BOO facilities under the old system, as well as with the one TOOR plant. It will also take TEAS's place in the power supply contract concluded between TEDAS and the TOOR distributors. Other market participants will include private-sector generators, industrial auto producers, private wholesale and retail traders, and eligible consumers. A new regulatory framework will be put in place to allow the market to function properly. An independent regulatory authority is to be established, governed by its own board, to apply non-discriminatory, transparent, stable and consistent regulation without day-to-day interference by the government. The regulatory authority will have the following functions (IEA, 2001):

- It will determine eligible consumers within the framework set by the act.
- It will apply and oversee a new licensing framework for market participants.
- It will enforce regulated third party access to transmission and distribution grids and develop and apply a new transmission and distribution code.
- It will regulate prices for any remaining captive consumers and oversee the transition towards the competitive market.

Fig. 9 Between 1973–2020, Final Consumption of Electricity by sectors in Turkey. Reproduced from IEA, 2005. International Energy Agency. In: Proceedings of the Energy Policies of IEA Countries: Turkey 2005 Review, Paris, France: IEA. *Negligible, **Includes commercial, public service and agricultural sectors.

Conclusion

From the viewpoint of energy sources such as petroleum and natural gas reserves, Turkey is not a rich country, but has an abundant hydropower potential to be used for generation of electricity.

Turkey must base its energy strategy on developing the whole hydroelectric potential as soon as possible. Turkey's main indigenous energy resources are hydro and almost all oil natural gas and high quality coal are imported. Therefore, in order to avoid foreign dependency both in sources and funds, Turkey must discover new and renewable energy resources.

Water and energy are the two important engines of sustainable development. In the energy sector, the basic policy of Turkey is the provision of cheap electrical energy on time and in sufficient quality and quantity. Investments in hydropower deserve special support as they are clean and have a long economic life-span.

It is important to point out the restructuring policies that are directing the development of new and renewable energy, and giving special emphasis to socio-economical bodies, laws and legal regulations. In this respect, particular attention and priority should be given to the development of the hydroelectric in Turkey, since it is the most important natural renewable resource and only 35% of the technically and economically utilizable hydro potential has been developed so far.

On the other hand, hydropower emits very few greenhouse gases in comparison with other large-scale energy options and thus helps slowing down global warming. In addition, by storing water in rainy seasons and releasing it in dry ones, dams and reservoirs help control water during floods and droughts. These essential functions, protecting human lives and other assets, will be increasingly important in the context of climate change is expected to give rise to even greater variability in the frequency and intensity of rainfall.

Introduction

Today's thermal barrier coatings (TBCs) are mainly manufactured with two different techniques. The first coatings brought into service were plasma sprayed coatings which are still in service. These coatings were first tested on commercial aircraft and owe their acceptance to success in this field. However, this success brought up a demand for research to achieve pioneer coatings that can serve in higher temperatures and more severe conditions. In cases where thermal cycle may happen, use of zirconia-based coating with high amount of monoclinic phase was proven to be inappropriate for structures (due to high volumetric change when transforming to martensitic phase). Porous atmospheric-pressure plasma-sprayed (APPS) zirconia-yttria ($\text{ZrO}_2\text{-Y}_2\text{O}_3$) on a plasma sprayed NiCrAlY bond-coat was introduced by NASA Lewis Research Center as an alternative way to overcome this handicap. This new technology is considered to be the onset of the thermal barrier coating research era (Miller, 1995; Toriz *et al.*, 1988).

Using yttria as a stabilizer for zirconia, using an oxidation resistant material (NiCrAlY) as bond-coat for base metallic material and lastly using the bond-coat system to eliminate the layer between ceramic and the base metal have been the most critical developments for the success of new coatings. Using metallic bond-coat as a replacement for the intermediate layer reduces stresses induced by material mismatch in thermal loading. However, mitigation of stresses due to material mismatch was not significant when exposed to higher temperatures since oxidation of the metallic bond-coat would be highly accelerated (DeMasi-Marcin *et al.*, 1990).

A new type of coating which was deposited using electron beam was developed in the late 1980s and became commercial in 1990s. Electron beam-physical vapor deposited (EB-PVD) zirconia-yttria coating was first used and tested in the burner rig lives and performance was reported to be much better than the performance of plasma sprayed entirely zirconia-yttria coatings (Sumner, 1980) and modifications in topcoat material made it possible to use these systems at higher temperatures (Bratton *et al.*, 1982; Stecura, 1979). Coatings deposited by electron beam technique owe their long life and durability to flexible columnar and porous structure, which makes it more strain tolerant. There are two types of porosities reported for these coatings, intra columnar and inter columnar vacancies. These porosities may disappear by sintering mechanism during service at high temperatures, but it is efficient enough to extend coating life by a considerable time.

Oxidation of the bond coat is often considered as one of the prime mechanisms that can lead to failure of TBC systems. Evans *et al.* (2001, 2008) claimed that due to anisotropic swelling of thermally grown oxide layer and uneven development of TGO layer residual stresses can rise and lead to nucleation of micro-cracks and thus become the dominant failure mechanism which can affect long-term durability of TBC systems. However, the mechanism through which oxidation occurs and different species travel through materials and meet to form TGO is pretty complicated and significant amount of research have been conducted to clarify this problem. For bond-coat alloys containing yttrium, diffusion of aluminum is affected by this reactive component, which decelerates diffusion of Aluminum cations, thus oxide components meet in the regions closer to substrate material (Balmain *et al.*, 1997). Consequently, presence of Yttrium leads to the formation of oxide mainly on the oxide-bond coat interface Fig. 1.

In contrast to classical models, where phase interface of a multi-phase system was investigated using discrete solutions with possessing severe computational challenges, Cahn-Hilliard (Cahn and Hilliard, 1958) and Ginzburg-Landau models treat these systems as continuous domains which brings certain ease to implementation of the model. In those approaches, free energy is defined to be a function of either species concentration or order parameter generally represented by ϕ and gradients of these parameters along with any other thermodynamic variable may also be included in the model. According to these theories, a previously predetermined interfacial energy for a restricted thickness is taken into account. It is also noted that the existence of free energy due to non-equilibrium of phases in the diffuse interface of two-phase system was not considered at the time. The treatment proposed by Cahn-Hilliard, Allen-Cahn, and Ginzburg-Landau are general equations that can be used in the fields with spatial variation of a parameter (Composition, density, etc.). Simulation of oxide formation process TBC systems has been a hot topic in the past decade and an extensive variety of models are available in the literature, and only few of them are tackling coupled multi-physics oxidation and failure problem in the same numerical framework. Ammar *et al.* (2009) have used Allen-Cahn phase field model to simulate oxidation and oxide propagation in the bulk metal. This model has the nature of flattening initial phase interface undulations. In the case of oxidation of bulk metal, initial surface undulation smoothing is observed in time. In contrast, when the coating is present on the metal, interface undulations maintain their shape during oxide growth due to material mismatches (He *et al.*, 2000). The most recent and inclusive model available is proposed and implemented by Loeffel and Anand (2011); Al-Athel *et al.* (2013), where a modified version of classical Fick's law for diffusion of oxygen through ceramic is used and thus the model generates a sharp interface of diffusing oxide in the bond coat.

In this work, a comprehensive model based on Allen-Cahn theory, which can retain undulations during growth of oxide through modifying a gradient term in the diffusion and phase field equation is proposed. The model is implemented in finite strain framework using ABAQUS user element subroutine (UEL) for finite element analysis (Fig. 1).

Fig. 1 Schematic diagram for diffusion of paths of components for formation of Alumina.

Balance Laws and Constitutive Equations

For an arbitrary material point with volume V and surface ∂v the coupled balance equations are presented at specific time t . Neglecting inertia effects, balance of momentum and forces, in current configuration for a spatial region can be expressed as,

$$\int_{\partial v} \mathbf{T} \mathbf{n} dS + \int_V \mathbf{b} dV = 0$$

Where $\mathbf{b}$, $\mathbf{T}$ and $\mathbf{n}$ represent body force, Cauchy stress and surface normal respectively. Thus, using divergence theorem for local balance, it can be written in the form below,

$$\text{Div} \mathbf{T} + \mathbf{b} = 0$$

Kröner's decomposition is initially used for the deformation gradient.

$$\mathbf{F} = \mathbf{F}^e \mathbf{F}^p$$

Where $\mathbf{F}^e$ is the elastic distortion which represents stretch and rotation and $\mathbf{F}^p$ is plastic distortion which is invariant with rigid body motions. From right polar decomposition $\mathbf{F}^e$ can be decomposed into right stretch $\mathbf{U}^e$ and rotation tensor $\mathbf{R}^e$

$$\mathbf{F}^e = \mathbf{R}^e \mathbf{U}^e$$

In this model the main strain measure is chosen as Hencky's strain due to good agreement with experiments for moderate deformation.

$$\mathbf{E}^e = \ln(\mathbf{U}^e)$$

Finally, Piola stress is expressed as

$$\mathbf{T}^e = 2G\mathbf{E}^e + K\text{tr}(\mathbf{E}^e)\mathbf{1}$$

Where G and K are shear modulus and bulk modulus respectively. Mandel stress which is the driving stress for plastic flow and the deviatoric part $\mathbf{M}_0^e$ are as below,

$$\mathbf{M}^e = \mathbf{F}^{eT} \mathbf{F}^e \mathbf{T}^e$$

$$\mathbf{M}_0^e = \mathbf{M}^e - \frac{1}{3} \text{tr}(\mathbf{M}^e) \mathbf{1}$$

Then using volume ratio which is expressed as

$$J = \det \mathbf{F}$$

Cauchy stress can be recalculated as follows

$$\mathbf{T} = J^{-1} \mathbf{R}^e \mathbf{M}^e \mathbf{R}^{e-T}$$

Equivalent tensile stress and plastic strain rate are,

$$\bar{\sigma} = \sqrt{\frac{3}{2}} |\mathbf{M}_0^e|, \quad \dot{\bar{\epsilon}}^p = f(\bar{\sigma}, S)$$

Parameter S is known as material resistance with initial value S_0 is defined to be a saturating type of function. Function g is defined to satisfy viscoplastic behavior for bond-coat and oxide material with $\dot{\bar{\epsilon}}_0$ and m defined as material parameters.

$$\dot{S} = g(\bar{\sigma}, S) = S \left(\frac{\dot{\bar{\epsilon}}^p}{\dot{\bar{\epsilon}}_0} \right)^m$$

For ceramic layer, it is assumed to have no plastic deformation due to brittleness of the material.

Phase change is tracked using a phase field parameter $0 < \phi < 1$, where 0 and 1 values for ϕ indicate un-oxidized metal and totally oxidized material respectively. Inelastic part of velocity gradient can be found as,

$$L^i = \dot{F}^i F^{i-1}$$

An inelastic stretch tensor can be expressed as,

$$D^i = D^s + (1 - \phi) D_{bc}^p + \phi D_{ox}^p$$

D_{bc}^p and D_{ox}^p represent stretching due to viscoplastic flow taking place in bond-coat and oxide respectively. As stated before $0 < \phi < 1$ is a function characterizing the relative extent of plastic flow at the interface. Plastic behavior of multi-phase materials is not well understood yet, thus a homogenization technique was used similar to Reuss/Sachs model for multiphase regions but in finite strain formulation.

Oxide growth is anisotropic process, for the reason that oxide tends to grow faster on metal interface approximately a hundred times faster than transverse direction. Consequently, D^s will be an anisotropic swelling tensor can be calculated using oxidation rate $\dot{\phi}$.

$$D^s = \dot{\phi} S$$

Swelling strain of the TGO can be defined as,

$$S = B_l m \otimes m + B_t (1 - m \otimes m)$$

S (Swelling concerning the principal direction of stress) is calculated using PBR (Pilling-Bedworth Ratio) (Chunhua and Wei, 2000) value with B_l for lateral and B_t for vertical growth direction with respect to interface normal vector m and $\otimes$ stand for dyadic of two vectors. For the numerical example demonstrated in Fig. 2, m is directly calculated from interface profile. Then, total inelastic deformation gradient is found to be

$$\dot{F}^i = D^i F^i$$

In Allen-Cahn theory it is assumed that local energy depends on, regional composition and interfacial composition of the environment as well as phase field. Cahn-Hilliard assumed that gradient of c (If the non-uniform field is chosen to be molar fraction of a definite phase) is small enough with respect to reciprocal inter-molecular distance that can be accounted to be an independent variable. The present model considers the gradient of the field variable ϕ , which leads to the definition of a free energy based on phase field and its gradient and additionally concentration of species, $\psi(c, \phi, \nabla \phi)$. Applying divergence theorem on Taylor expansion of the free energy function and neglecting species inlet from boundary surface one can write a specific form Helmholtz free energy as below,

$$\psi(c, \phi, \nabla \phi) = n \int_V \left(\psi_0(c, \phi) + \frac{1}{2} \alpha \nabla \phi \nabla \phi \right) dV$$

Fig. 2 TGO growth after 10 h (left) and 100 h (right).

ψ , c and n are free energy, normalized species concentration, number of molecules per unit volume respectively. Time evolution of phase field is expressed as

$$\beta \dot{\phi} = \alpha \Delta \phi - \frac{\partial \psi_0}{\partial \phi}$$

Where α and β are parameters used to control interface thickness and velocity. Chemical potential μ and species flux j are defined as below,

$$\mu = \frac{\partial \psi_0(c, \phi)}{\partial c}$$

$$j = -M(\phi) \nabla \mu$$

With M defined as mobility of the species. Then classical Fick's law for diffusion of species can be written as,

$$\dot{c} = \text{div}(M(\phi) \nabla \mu)$$

Coupling between diffusion of oxygen and deformation should be a two-way coupling in order to deaccelerate diffusion in compressed medium and vice versa. The oxide diffusion-imposed bulging is performed by adding a swelling stretch term D^s into inelastic stretch tensor D^i . Strain induced diffusion coupling is defined to be sensitive to the magnitude of $\text{tr}(\epsilon)$. Adding this term to the free energy of the system as an independent variable requires the calculation of gradient of this term. The gradient is calculated through the solution of the following trivial balance law, where a scalar variable P is defined as a new degree of freedom.

$$P = \text{tr}(\epsilon)$$

A specific form of free energy is assumed to have the following form,

$$\psi_0(c, \phi) = \phi^2(3 - 2\phi)\psi_1 + (1 - \phi^2(3 - 2\phi))\psi_2 + \chi\phi^2(1 - \phi)^2 - KP(c - c_0)$$

$$\psi_i(c) = \frac{1}{2}k_i(c - c_i)^2 \quad i = 1, 2$$

k and χ are material phase curvature and a parameter relate to free energy function respectively. Material properties are also defined to be dependent on phase field variable.

$$K(\phi) = K_{ox}\phi + K_{bc}(1 - \phi)$$

$$G(\phi) = G_{ox}\phi + G_{bc}(1 - \phi)$$

$$M(\phi) = M_{ox}\phi + M_{bc}(1 - \phi)$$

Numerical Implementation

The theory and model presented, are implemented as an implicit user element subroutine (UEL) code in ABAQUS finite element software. The element was designed as a two dimensional four-noded linear isoparametric element. Balance equations solved through the numerical process are presented below.

$$\text{Div}T + b = 0$$

$$\dot{c} = \text{div}\left(M(\phi) \nabla \left(\frac{\partial \psi_0(c, \phi)}{\partial c}\right)\right)$$

$$\beta \dot{\phi} = \text{div}(\alpha \nabla \phi) - \frac{\partial \psi_0}{\partial \phi}$$

M and α are written in tensorial form and transverse components are defined to be zero in order to prevent lateral propagation of oxide. This modification supports the experimental results claiming negligible growth in lateral direction against rapid vertical growth of TGO.

$$P = \text{tr}(\epsilon)$$

Defining,

$$a = k_1\phi^2(3 - 2\phi) + k_2(1 - \phi^2(3 - 2\phi))$$

$$b = k_1(c - c_1) - k_2(c - c_2)$$

And choosing N^A as a shape function for interpolation in node A, residual vectors for phase field and diffusion equations are expressed as,

Fig. 3 (a) Results for (top-left) thermally grown oxide (top-right) stress in x direction (bottom-left) stress in y direction and (bottom-right) Plastic strain after 10 h of oxidation (b) Boundary conditions and schematic of the geometry.

$$R_c = \int_e \left(N_A \dot{c} - a \nabla N_A \cdot M(\phi) \nabla c + 6M(\phi)b(1-\phi) \nabla N_A \nabla \phi + 3KN_A P \right) dV - \int_{\partial e} N_A \mathbf{j} \cdot \mathbf{n} dS$$

$$R_\phi = \int_v \left(N_A \beta \dot{\phi} + \nabla N_A \cdot \alpha \nabla \phi + N_A (3\phi(1-\phi)C + \chi D) \right) dV + \int_{\partial e} N_A \epsilon \cdot \mathbf{n} dS$$

$$R_e = \int_e N_A (P - \text{tr}(\epsilon)) dV$$

Where ϵ is an energy conjugate for $\nabla \phi$ and scalar values C and D are defined as,

$$C = k_1(c - c_1)^2 - k_2(c - c_2)^2$$

$$D = 4\phi^3 - 6\phi^2 + 2\phi$$

Dominant terms of the global tangent tensor is also found to be in the following form.

$$K_{cc}^{AB} = - \int_e \left(\frac{N_A N_B}{\Delta t} + aM(\phi) \nabla N_A \nabla N_B + N_B 6M(\phi)b(1-\phi) \frac{\partial b}{\partial c} \nabla N_A \nabla \phi \right) dV + \int_{\partial e} N_A N_B \frac{\partial \mathbf{j}}{\partial c} \cdot \mathbf{n} dS$$

$$K_{\phi\phi}^{AB} = - \int_e \left(\beta \frac{N_A N_B}{\Delta t} + \alpha \nabla N_A \nabla N_B + N_A N_B \left(3(1-2\phi)C + \chi \frac{\partial D}{\partial \phi} \right) \right) dV - \int_{\partial e} N_A N_B \frac{\partial \epsilon}{\partial \phi} dV$$

$$K_{ee}^{AB} = - \int_e (N_A N_B) dV$$

Analysis and Results

A medium with two distinct material properties was modeled with a sinusoidal interface to resemble ceramic top-coat and bond-coat alloy. Layers are designed to have 150 μm thickness (average ceramic coating thickness) and 30 μm width. 0.5 μm size meshes were chosen for TGO propagation around the interface and coarser meshes were used in distant regions. Mechanical boundary conditions are presented in Fig. 3 for an isothermal analysis at 1423 K. Bond-coat material is assumed to be FeCrAlY. Parameters utilized for different material layers in the analysis can be found in the Table 1.

As illustrated in the figure below transverse isotropy is assumed for top-coat due to the special columnar structure of the EB-PVD coating. A $\tanh$ type function was given as initial condition for phase field in the interface with $\phi = 1$ in ceramic and

$\phi = 0$ in bond-coat. Initial concentration was defined to be zero in bond-coat and one in ceramic. As interface propagates into bond-coat region, actual new phase with distinct material properties will start to grow. Analysis results for TGO growth, stresses (MPa) for 10 h of service can be found in the flowing figure.

Growth of oxide phase with a definite interface thickness can also be clearly observed in the figure below. Interface thickness is defined to be approximately 4 μm but it will be physically more feasible to reduce it to a smaller region to mimic a sharp interface in oxidation process. In order to satisfy mesh independency of the problem a certain number of elements should be used. For this analysis an interface with 5 elements with 2.5 μm width is used.

The model validation is performed through comparing numerical and experimental results available for EB-PVD oxidation (Tolpygo *et al.*, 1998) (Fig. 4).

Concluding Remarks

In this study, development and growth mechanism of thermally grown oxide resulting local inelastic deformation is modeled on the base of Allen-Cahn phase field model. A fully coupled formulation in finite deformation framework is implemented using ABAQUS finite element program and validated for EB-PVD FeCrAlY type thermal barrier coatings. The model parameters are calibrated for experimental results available for TGO thickness evolution in time. The stress contours are observed to be in good agreement with other studies showing concentration of stress in uphill and downhill regions of the undulations. Moreover, the magnitude of internal stress generated in the bond-coat exceeds GPa level after a certain service time as reported in the literature (Al-Athel *et al.*, 2013). A considerable amount of plasticity generated in the bond-coat region due to growing oxide is demonstrated in Fig. 2. It is considered that those results could be a good base for an additional step of including a failure mechanism to the model for the life time estimation of the coating system.

PREFACE

The *Encyclopedia of Renewable and Sustainable Materials* is a novel initiative, launched to cater for researchers, industrial practitioners and environmental conservationists to bring to the fore the issues of renewability, regeneration, recyclability and sustainability of natural material resources for the greater good of the environment, society and renewable resources. With these objectives the project was constituted of 11 sections, led by one Section Editor each. There are about 4,000 printed pages, accommodated in five volumes ranging from 600 to 1000 pages each.

This encyclopedia is the primary reference source for researchers at different levels and stages in their career in academia and industry and those with an interest in environmental protection and sustainability, including re-use and recycling of natural and synthetic materials and regeneration of natural materials. The work encompasses the knowledge and understanding of many experts into a single, comprehensive work of about 370 articles comprising a combination of review articles, case studies and research findings resulting from research and development activities in both industrial and academic domains. The encyclopedia, focuses on how some of these topics bring advantages for a broad range of technologies and environmental protectionists. These include harnessing existing materials both natural and synthetic, their re-usability and regeneration possibilities for the greater good of society and the environment. The aspects of feasibility, conservational objectives and practicability of implementation have been addressed through a number of relevant articles.

As Editors in Chief of this five-volume comprehensive publication, a truly collaborative work, we are greatly indebted to the 11 Section Editors who are internationally renowned experts in their fields, for guiding and selecting the topics for their respective sections which constitute the five volumes, commissioning authors and reviewing the contents so meticulously. Their true dedication to the scientific community and society is reflected in the time and energy they have given to this project. My sincerest thanks are due to all the authors – researchers, environmental protectionists and practitioners who have contributed extensive coverage of literature review as well as recent works of research to this substantial five volume encyclopedia. The excellent insight and specialist knowledge in their respective fields is reflected in the high quality content of this unique work.

Both of us and all the section editors are greatly appreciative of all the hard work undertaken by all concerned to turn this concept of the *Encyclopedia of Renewable and Sustainable Materials* into a publishable work. Our special thanks go to Ruth Rhodes and Michael Nicholls, the Project Manager, along with Kshitija Iyer and the rest of the team at Elsevier who served successively to keep the project on track through friendly nudges in order to ensure timely completion. We are also hugely grateful to other colleagues at Elsevier production unit for the coordination of the proofs.

The extensive research treatment of core ethos of renewability, recyclability and regeneration, supplemented by applied case studies has drawn together many areas of research and we sincerely hope that this work will prove to be of great help to both the young and experienced members of the international research community, academics and industrial practitioners associated with sensible utilization of natural and synthetic materials for many years to come.

Saleem Hashmi and Imtiaz Ahmed Choudhury
Editors in Chief – *Encyclopedia of Renewable and Sustainable Materials*

CONTENTS OF VOLUME 2

Editorial Board	v
List of Contributors to Volume 2	vii
Preface	xiii

Natural Renewable Materials

Bamboo Versus Tubular Steel Scaffolding in Construction: Pros and Cons <i>Paul O Awoyera and Anthony N Ede</i>	1
Biogas Production From Solid Waste Landfill <i>Ivan FS Santos, Regina M Barros, and Geraldo L Tiago Filho</i>	11
Biopolymer-Based Composites for Medical Applications <i>Sathish S Dhilip Kumar, Nicolette N Houreld, and Heidi Abrahamse</i>	20
Biopolymers in the Synthesis of Different Nanostructures <i>Mohammad ET Yazdi, Mohammad S Amiri, and Majid Darroudi</i>	29
Characterization of Wood, Cork and Their Composites for Building Insulation <i>Pragya Gupta and Pradip K Maji</i>	44
Dry/Solid-State Fermentative Ethanol Production <i>Maryam Molaverdi, Safoora Mirmohamadsadeghi, and Keikhosro Karimi</i>	60
Effect of Temperature Dependence of Sorption on Hygrothermal Performance of a Hemp Concrete Building Envelope <i>Anh D Tran Le, Driss Samri, Omar Douzane, Geoffrey Promis, Anh T Nguyen, and Thierry Langlet</i>	68
Energy and Acoustic Performances of Timber in Buildings <i>Marco Caniato, Federica Bettarello, and Andrea Gasparella</i>	78
Environmental Assessment of Green Buildings <i>Pervez H Shaikh, Muhammad S Shaikh, Mahesh Kumar, Faheemullah Shaikh, Muhammad A Uqaili, and Inamullah Bhatti</i>	92
Green Buildings: Risk Factors and Mitigation Measures/Emerging Urban Green Spaces in Dhaka: Planning and Analysis <i>Manifa Rehnuma</i>	98
Green Energy Fuel From Biomass and Sea Water <i>Muhammad B Tahir, Muhammad I Khan, Muhamad Pervaiz, Sidra Arif, Mudassar Maraj, and Muhammad Sagir</i>	114
Green House Effect and Carbon Foot Print <i>Muhammad S Shaikh, Pervez H Shaikh, Khadija Qureshi, and Inamullah Bhatti</i>	120
Hydrogen Evolution Using Advanced Technologies Based on Photocatalysis and Plasma <i>Muhammad B Tahir, Abdullah M Aasir, Muhammad Sagir, Sidra Arif, Ghulam Nabi, Muhammad Rizwan, and Amber Batool</i>	126
Hydrogen Production Through Water Splitting Using Nanomaterials Under Solar Energy <i>Muhammad B Tahir, Tuheed Zahra, Tahir Iqbal, M Rafique, M Shakil, and Muhammad Sagir</i>	132
Jute Pulping: Opportunities and Challenges <i>M Sarwar Jahan and AFM Akhtaruzzaman</i>	136

Life Cycle Assessment of Sisal Fiber <i>Ayyannan Devaraju and Rajasekar Harikumar</i>	144
Nanocellulose Based Aerogels for Varying Engineering Applications <i>Deepu A Gopakumar, Shilpa Thomas, Owolabi F.A.T, Sabu Thomas, Ange Nzihou, Samsul Rizal, and HPS Abdul Khalil</i>	155
Natural Fiber Composites: Review of Recent Automotive Trends <i>S Witayakran, W Smitthipong, R Wangpradid, R Chollakup, and PL Clouston</i>	166
The Nexus Between Biomass – Footprint and Sustainable Development <i>Faik Bilgili and Recep Ulucak</i>	175

Bamboo Versus Tubular Steel Scaffolding in Construction: Pros and Cons

Paul O Awoyera and Anthony N Ede, Covenant University, Ota, Nigeria

© 2017 Elsevier Inc. All rights reserved.

Introduction

Structural scaffold is a temporary structure used during building construction or repair of exteriors or interiors to support movement of people and materials. In most nations of the world, the construction industry is a booming sector of the economy and the demand for scaffolding formwork for the maintenance of existing building stocks and construction of new low-rise and high-rise buildings is high. It is estimated that scaffolding works normally share about 1% of a construction project budget, which can be a considerably high in large projects.

Scaffolds perform an important role in ensuring the process of different works in a construction project. Thus, owing to the significance of scaffolding in buildings, it therefore becomes essential to know the nitty-gritty of the various materials mostly used for this purpose.

There are a multiplicity of scaffolding systems, both traditional imported ones, with each system having its pros and cons in terms of cost and safety performances. The three prevailing scaffolding systems established internationally are bamboo scaffolding, metal (steel) scaffolding, and mixed scaffolding.

Good use of metal scaffolds applies structural design principles for spacing, layout of components, and foundation stability in relation to the self-weight of structural elements to be supported, and environmental and operation loads imposed on the falsework system. In scaffolding, we are concerned with combined stresses of bending and buckling for which the cross-sectional shape becomes of overriding concern. All steel scaffolding has always been made from tubes, same as bamboo, though the shape of steel is fixed, while that of bamboo is adaptable. The multidirectional resistance of tube to buckling is excellent. Favorably, in a scaffolding, cross-bracing is an extra usual means of preventing buckling. Moreover, bamboo supports its own weight and resists bending loads from wind. These similarity in shape and resistance have contributed to the use of bamboo for scaffolding.

Over the years, both bamboo and the tubular steel scaffolding have been used during construction of buildings, and as such, there are various experiences that constructors have while using these materials. Therefore, this article focuses on exploring the application of both scaffolding materials with emphasis on their pros and cons.

Overview of Scaffolding Materials

Basic Components of Scaffolding

During construction of buildings, irrespective of the height, scaffolding is mostly used to provide external structural support for both the building-in-progress and the people working on it. Different materials, such as metal piping, tubes, and bamboo, are used for scaffolding, in addition to couplers and boards. However, regardless of type and quality of material, scaffolding must satisfy the standards for performance requirements and structural design methods. The scaffolding member needs to be compatible with a wide array of buildings and structures, because there are various kinds of scaffolds that fit specific building requirements.

The scaffolding materials can vary based on building type or constructor choice, however, the scaffolding process is comprised of the same basic elements. Only the manner in which the elements are designed and coupled together may vary.

There are three basic scaffolding components, these include standards, ledgers, and transoms. The standard is usually a long pipe, tube, or bamboo that connects the mass of the scaffold directly to the ground, this runs through the length of the scaffolding. The base of each standard is connected to a base plate that aids distribution of the overburden weight resisted by each standard across the ground. The ledger runs horizontally in between each standard, which further support weight distribution. Lastly, the transom is usually connected on top of the ledgers at a right angle; this may come in several different forms. The transom holds the standards in position as well as supporting the boards. [Fig. 1](#) shows the basic components of a scaffolding system.

There are other smaller supportive components used in scaffolding besides standards, ledgers, and transoms. These elements include braces (cross braces and façade braces) and couplers, which serve to reinforce the basic scaffolding members. The braces are used to hold ledgers diagonally (cross braces). The braces are securely attached to the standards to increase the overall rigidity of the structure and also prevent the structure from swaying.

The couplers are used to connect the structural elements, whether to connect a ledger or transom to a standard, a right-angle coupler, just as the need may be.

Metal Scaffold or Tubular Scaffold

Metal scaffolds are formed by steel tubes joined by couplers and the most common type is the tubular scaffold. The Hong Kong Code of Practice for Metal Scaffolding Safety given by the [Labour Department \(2001\)](#), stipulates that steel tubular scaffolds be constructed in tubes and couplers based on the design and drawings of professional engineer. A steel tube is expected to have a

yield stress equal or greater than 235 N/mm^2 with an outside diameter of 48.3 mm and a wall thickness of 4 mm. Steel scaffold can be properly engineered, accurately designed and effectively tested for the envisaged height and load. It has the advantage of being properly planned for safety with less risk of cost cutting and it requires far less skilled labor. It has customized accessories like wheels and ladders that fasten securely to the frame system and the walk boards are hooked securely as well.

Several forms of tubular scaffolds are in use, but the most common is the single-pole scaffold or putlog scaffold and the independent tied scaffold (Pallett and Nicoll, 2015).

Putlog scaffold

This single-pole scaffold system consists only of a single row of vertical standards tied parallel to the face of the building. The standards are set away from the building façade at a distance so that working platforms can be accommodated in the space between the row and the building façade, with its inner edge as close to the façade as practicable. The scaffolds shown in Fig. 2 are held to the building structure by horizontal members called putlogs. This form is usually used for light duty.

Independent tied scaffold

This form has two rows of standards parallel to the building. Boards and toe boards are accommodated in between the rows to form a working platform. This type of scaffold does not rely on the building for support and is therefore suitable for use in conjunction with frame structures.

A structure of an independent tied scaffold is shown in Fig. 3.

Typical Design Consideration for Steel or Bamboo Scaffolding

Generally, the design of a scaffold should normally take into consideration:

- Strength, stability, and rigidity of the supporting structure;
- Handling normally associated with scaffolding; and
- Safety of persons engaged in the erection, alteration, use, and dismantling of the scaffold.

However, scaffolding design should involve consideration for load support or access by construction workers, based on the design standard.

Similar to the case of building design, the design of scaffolding can be categorized into load estimation, assessment of components, and provision for support. The load consideration for scaffolding includes:

- Dead loads – these loads are permanent on the scaffold through its service life. They include self-weight of the scaffold structure and components including working platforms, catch platforms, access platforms, stairways, ladders, screens, sheeting, platform brackets, suspension ropes, secondary ropes, traversing ropes, tie assemblies, scaffolding hoists, electrical cables, and any other permanent attachments.
- Live loads – these are moving loads on the scaffold, including weight of persons, weight of materials and debris, weight of tools and equipment, and impact forces.
- Environmental loads – these include loads impacted on the scaffold due to the effect of wind, snow, earthquake, rain, and ice.

Thus during design, scaffolding should be loaded for the most adverse combination of dead loads, live loads, and environmental loads that can reasonably be expected during the period that the scaffold is expected to be in service. This is done by introducing a minimum factor of safety, which is usually four. That is, the design load is multiplied by a factor of 4, before and determining limiting strength and yield stress of the metal used in the engineering design of scaffolds and their components. Using the factor of safety ensures that scaffolds and their components can support four times the maximum design load without experiencing failure.

Generally, design of scaffolding should take into consideration the following conditions:

Fig. 1 Basic components of scaffolding.

Fig. 2 Structure of metal putlog scaffold. Reproduced from The Constructor, 2017. Types of scaffolding in construction. Available at: <https://theconstructor.org/building/types-of-scaffolding-in-construction/11845/> (accessed 05.06.17).

Fig. 3 Structure of independent tied scaffold. Reproduced from Penketh, C., 2014. Scaffold management and update. Available at: <http://www.ncsg.org.uk/> (accessed 05.06.17).

1. Adequate estimation of the loading conditions or combination of different loads on the structure (dead, live, wind, and snow load).
2. Scaffolding elements must be checked to ensure they can sustain the required loads.
3. Both the stability or rigidity of the scaffold system must be ensured by adopting a standard safety factor.
4. Adequate foundation must be installed for the scaffolding elements. A timber sole plate, not less than 200 mm × 38 mm × 500 mm long, can be used as foundation support for scaffolds. However, materials, such as bricks and blocks, are not suitable for this purpose because they are loose material that can easily crumble or be driven into the ground.

Design fundamentals

There is currently a standardized design approach for steel scaffolding as a result of rapid development in its usage. However, the unavailability of standard design codes for bamboo scaffold has created limitations in this regard. As a result, the majority of bamboo users mostly rely on their previous experience with the material during practice. In this section, a typical design consideration of a tubular steel scaffolding is presented.

Load estimation is an integral part of scaffolding design. Two major load types to be considered in scaffold design are:

- Steadily applied load, such as scaffold self-weight, dead load from permanent structures, wind load, access load, and thermal load.
- Dynamic load, such as vibration, surge, or impact resulting from pouring of concrete, plant movement, or vehicles.

British standard (BS 5973, 1993) provides a detailed loading specification to be considered for a steel tubular scaffolding design. The equivalent uniformly distributed load for a metal scaffolding ranges from 0.72 kN/m² for class 1 to 6.0 kN/m² for class 6. However, classes 4 or 5 are for operational load (such as one worker, concrete or 9-inch brick), which is 3.0 kN/m².

Wind load is represented in the form of pressure exerted on the scaffolding system. The code specifies maximum design wind pressure as 770 N/m², while a working wind is 200 N/m².

For example, the wind pressure exerted per unit length of a 48.4-mm-diameter tubular steel is taken as 37.0 N/m² from the code.

The safe strut permissible stress can be determined using the Perry–Robertson formula (see Eq. 1) provided in appendix B of BS 449-2 (1969). Thus, for a tubular mild steel of grade 43, having 48.4 mm outer diameter and 4.08 mm thickness and a Young's modulus of 206 kN/mm², the safe strut load for an effective length of 1.8 m is 36.5 kN.

$$K_2 \times P_c = \frac{Y_s + (\eta + 1)C_o}{2} - \sqrt{\left[\left\{ \frac{Y_s + (\eta + 1)C_o}{2} \right\}^2 - Y_s \times C_o \right]} \quad (1)$$

where P_c is the permissible average stress (in N/mm²). K_2 is a coefficient to allow for lack of straightness in addition to h , together with lack of square ends and some corrosion. Y_s is the minimum yield stress (in N/mm²). C_o is the Euler critical stress (in N/mm²).

$$C_o = \frac{\pi^2 E}{\left(\frac{l}{r}\right)^2} = \pi^2 \frac{210,000}{\left(\frac{l}{r}\right)^2} \quad (2)$$

where η is a constant. l is the effective length (in m). r is the effective radius of gyration (in m). l/r is the slenderness ratio.

For instance, in fittings and auxiliaries, such as the base, a safe working load of 65 kN is recommended by standard.

According to BS 5973 (1993), parameters required for an elastic design of scaffold are given as follows, using Eqs. (3)–(5):

$$n = \frac{2P - W}{s} \quad (3)$$

$$h = n \times \text{the lift height} \quad (4)$$

$$H = \frac{h}{C} \quad (5)$$

where s is the self-mass of the scaffold per lift/bay (in kg). w is the extra mass on all the working lifts in a single bay (in kg). W is the total extra mass of all the working lifts (in kg). P is the allowable load in a standard (in kN). n is the number of lifts. h is the calculated height of the scaffold (in m). C is the safety coefficient. H is the recommended height of the scaffold after the application of the factor C (in m). $W + ns$ is the required strength for two standards, which is equivalent to $2P$.

As an example, the height of scaffold required for a three lengths of bay, 2.1, 2.4, and 2.7 m, of a very light duty scaffold, having one working platform that is rated at 0.75 kN/m² with three boards wide and in 2-m lifts, is estimated as shown in Table 1.

Bamboo Scaffold

Bamboo scaffolding is a type of scaffolding made from bamboo and has been widely used in building work for ages. It is an ancient structural system, having been used in China for a few thousand years, and in more recent decades it has been well developed in Hong Kong. Bamboo scaffolding is a slender structure of natural bamboo pieces (Shing, 2009).

Bamboo is the fastest growing grass and it grows in large quantities in the tropical regions of Asia and in Africa. It is cheap in regions where bamboo plant is locally available. It is the cheapest scaffolding material and is readily available in the tropical regions and a few well-developed nations in Asia. It requires a special skill by cheap semiskilled labor to place it properly and is suitable for small projects. Good-quality bamboo can be used multiple times, which reduces the cost of construction. It has been

Table 1 Design results

Bay length (m)	S (Kg)	W (Kg)	P (kN)	n	h (m)	C	H (m)
2.1	76	182	24.9	64.4	128.8	1.64	78.54
2.4	78	205	24.9	62.5	125.0	1.62	77.16
2.7	81	229	24.9	59.8	119.6	1.60	74.75

Source: Adapted from BS 5973, 1993. Code of Practice for Access and Working Scaffolds and Special Scaffold Structures in Steel. London: British Standard.

verified that quality bamboo has a good tensile strength, which makes it comparable to the steel used in most scaffolding, but that inconsistent bamboo quality can cause problems. Bamboo is also cheaper, which has made it more attractive in most developing nations and advanced nations where the use is permitted. Bamboo is a fibrous material too, so it makes sense that it can be as strong as many other natural fibers. It has been verified that bamboo has tensile strength in the range of 156–185 N/mm², which is impressive and certainly implies a greater strength to weight ratio than steel, and it is flexible. It's half the weight of steel. Despite being lightweight, some stronger species of bamboo will actually compete favorably with steel. Bamboo scaffold design is highly approximate and based more on the experience of the fabricator. With a bamboo scaffold, the ladders are tied to it and the walk board RESM-S are just laid unfastened on the cross beams and can easily slip off leading to great safety risk. It is cost effective and quite safe if properly built. But for it to be safe, it must be over designed to consume more materials, therefore tending to be expensive, while the realities of cost cutting and lax oversight can lead to severe fatalities. Bamboo is a viable choice where highly skilled workers are cheap. It is not easily reusable, actual strength varies with great uncertainty, it is not suitable for big projects, and is less trustworthy than metal scaffolding. During arrangement of bamboo scaffolds, strong nylon fiber straps are used to tighten bamboo shoots together, thereby forming a solid and secure scaffold structure using no screws. Bamboo scaffold does not have a solid foundation and anchorage base on the ground, thereby creating a great risk for instability.

There are two common types of bamboo scaffolding systems in the building industry, one of the most developed in the world: the single-layered and double-layered bamboo scaffolds.

Components, selection, erection, maintenance, and dismantling of bamboo scaffolds

Bamboo scaffolding system is used in similar manner as the steel scaffold, so the components are similar, however there is variation in terms of coupling of bamboo members. The traditional means of coupling bamboo members is by tying using strong nylon, but steel scaffolds are developed with the use of standard couplers at joints. Recent advancement in technology is providing solutions that can ensure a more systemic coupling of bamboo members.

The selection of bamboo for scaffolding is primarily based on its strength development at maturity, although this property can vary among different species. The strength of bamboo comes from its vascular bundles within the main matrix of the culm. Bamboo tends to perform poorly, when loaded perpendicularly to its grain direction, and its strength diminishes with increasing moisture content.

The erection process of bamboo scaffolds in building is slightly different compared to steel scaffolds. In the case of bamboo, the bracings are extended from the base to the top of the scaffolds. This helps to ensure that bamboo scaffolds are effectively braced and tied back to ascertain overall stability of the structure. Also, knotting between bamboo members must be tight and secure.

Safety during construction is a concern to building workers, so there must be a periodic inspection and maintenance of bamboo scaffold during construction. Bamboo, being a natural material, can expand and contract as the moisture content changes. Therefore, close supervision and frequent inspection is required in order to ensure the structural integrity of the bamboo scaffolds. The inspection is more needed when there is rainfall or wind at the building site. This procedure can help to prevent unnecessary accidents during construction.

Immediately after a project has been completed, it is important that the bamboo scaffold be dismantled to avoid exposing it to deterioration as a result of changing weather conditions. Normally, dismantling of the scaffold should start from the building's topmost level and downward, first removing the noncritical members before the critical ones. Bamboo must be stored appropriately after dismantling, in a place free from moisture.

Bamboo scaffolding: A case study from Hong Kong

Regardless of Hong Kong's predominantly modern architecture, it still sticks with bamboo scaffolding over steel counterparts in new construction or renovation of high-rise residential blocks or commercial buildings. The attractive factors that have made bamboo scaffolding an overwhelming choice in Hong Kong over steel materials are cost, time, and durability. Bamboo is locally available and cheap. Time is very important in Hong Kong and bamboo scaffolding has great advantage over steel for putting up and for taking down by the Hong Kong scaffolder specialists. This time savings is attributed to the presence of skilled bamboo scaffolders. As of 2013, there were 1751 registered bamboo scaffolders and roughly 200 scaffolding companies in Hong Kong, many of whom are members of the Hong Kong & Kowloon Scaffolders General Merchants Association Limited.

In Hong Kong, building construction crews use bamboo instead of steel to construct scaffolding up to 50 stories high (Chavan, 2001). Bamboo scaffolding is being used to build apartment blocks, repair walls, and refurbish neon signs because bamboo is cheaper, lighter, more flexible, and takes less time to erect and dismantle than steel scaffolding. Scaffolders in Hong Kong are of the opinion that properly erected and maintained bamboo scaffolding can be as strong and as safe as steel or aluminum structures. But construction workers here have one of the highest fatality rates in the developed world.

Bamboo scaffolding was first introduced into the modern building industry in Hong Kong prior to British colonization in the 1800s. The three major types of scaffolding in Hong Kong are double-row scaffold, extended bamboo scaffolding, and shop signs of bamboo scaffolding. The success story of bamboo scaffolding in Hong Kong can be attributed to the government regulation of the bamboo scaffolding trade and abundance of skilled bamboo scaffolders.

Trend of gradual decline of bamboo scaffolding in Hong Kong

Of the more than 1751 registered bamboo scaffolders and roughly 200 scaffolding companies recorded in Hong Kong in 2013 (Saurin and de Macedo Guimarães, 2006), the use of bamboo scaffolding in Hong Kong is beginning to diminish due to safety risks, as well as shortages in labor and material. Safety risks of bamboo scaffolding are very high due to so many variabilities and

Fig. 4 Structure of single-layered bamboo scaffold. Reproduced from Yu, W.K., Chung, K.F., Chan, S.L., 2003. Column buckling of structural bamboo. *Engineering Structures* 25 (6), 755–768.

uncertainties in bamboo material, accessories, design approach, and fabrication methods. The labor shortage may be due to the unwillingness of younger generations to take up the scaffolding trade due to high accident risk, unsafe work environment, and unwillingness to procure professional license from the Hong Kong Construction Industry Council. Actual and future bamboo material shortage is also a contributing factor to the decline bamboo scaffolding in Hong Kong. The bamboo scaffolding material is imported to Hong Kong from mainland China. The fear of uncertainties related to possible blocked supplies due to export embargoes and environmental concerns remain high.

Single-layered bamboo scaffold

This is made up of a single plane of framework (Wang, 1998), which is commonly known as the working scaffolds. It is usually erected at about 750–900 mm from the building face. This type of scaffold is shown in Fig. 4. Single-layered bamboo scaffold is mainly used for light site works, such as exterior decoration, platform for rebar workers, and for boundary fencing during the construction stage. It is highly flexible for sites, cheaper, causes less obstruction to work in progress, and easy to mount and dismantle. However, it poses high safety challenges due to high risk of instability. For instance, in Hong Kong, the use of single-layered scaffolds has been banned in the construction stage of buildings (Shing, 2009), due to its associated safety concerns.

Double-layered bamboo scaffold

This type of bamboo scaffold consists of two layers: the inner layer or the finishing scaffold, which is usually erected at about 150–300 mm from the building face, and the outer layer or working scaffold, erected at about 600–700 mm from the inner layer, as can be seen in Fig. 5. Double-layered scaffolds permit more complex jobs to be executed at greater heights more safely (Shing, 2009). This is the Hong Kong Government's approved bamboo scaffold since it offers greater safety for the workers and a means to reduce the rate of accidents and fatalities (Wang, 1998).

Life cycle of bamboo scaffold

Bamboo scaffolding systems, as a renewable resource, are used during construction in most developing countries. They can be easily assembled using a simple repetitive design, and can be used effectively for up to a five-story building. Just like a steel scaffold, bamboo scaffold is also recyclable. A typical life cycle of a bamboo scaffolding system is shown in Fig. 6. There is need to periodically inspect and maintain bamboo scaffold when it is in use until when the project is completed. At the end of a particular project, it can be possible to reuse bamboo scaffold for another project, if it is assessed and found suitable, i.e., showing no significant sign of deterioration.

Fig. 5 Structure of double-layered bamboo scaffold. Reproduced from European Commission, 2016. New bamboo engineered biomaterial sustainable building components. Available at: <http://europa.eu/geninfo/query/resultaction.jsp?QueryText=bamboo&swlang=en&x=0&y=0> (accessed 23.05.17).

Fig. 6 Life cycle of bamboo scaffolding system.

Pros and Cons of Bamboo and Tubular Steel Scaffolds

Uses and Associated Building Failures

There is an open competition that is common with bamboo and many metal scaffolding systems, mostly imported from different countries all over the world. Users of these materials consider a number of factors before making a choice on what material to be used for scaffolding.

In most developing countries of the world, mostly where there are abundant bamboo plantations, bamboo scaffold has been one of the most preferred access scaffolding systems during building construction. Apart from Hong Kong, bamboo scaffolding is mostly seen in many developing Asian countries, such as India, Bangladesh, Sri Lanka, Indonesia, and most of the nations of Africa, such as Nigeria, Cameroon, and Ghana. Tropical rain forest regions of African and Asia countries are the home of bamboo,

Fig. 7 Partial collapsed of a building under construction in Ikeja, Nigeria. Reproduced from Akoni, O., Olowoosopejo, M., 2012. 5 Escape Death as Building Collapses in Lagos. Valley Forge, PA: Vanguard.

which matures after 3 years to the required wide thickness and dense skin perfect for scaffolding. The supply of bamboo is highly sustainable in the tropical regions as long as a replanting strategy is in place to replace the harvested stock. In many African countries, notably Nigeria, bamboo scaffolding is commonly used in large-scale construction in rural and urban areas. In fact, bamboo is an essential building and construction commodity in Nigeria due to the abundance from the tropical rain forest, thus there is no shortage of bamboo, and its sustainability is not an issue, since new bamboo trees are continually being planted. Meanwhile, tubular steel scaffolds are mostly used in developed nations of the globe, due to their advancement or because they have no bamboo availability. There is increasing growth in tubular steel scaffold all over the world, however, pressure to clear vegetation to make room for more habitation for the teeming population and the trend to build high in developing nations with low-skilled manpower could reduce the use of bamboo scaffolding in future.

It is well known that a typical height of bamboo scaffolds is about 15 m, but on the other hand the installation of steel bracket supports at regular intervals is able to cover the full height of the building. Although the tubular steel scaffolds are erected based on technical design specifications, erection of bamboo scaffolds is generally done by scaffolding practitioners, mostly without using any technical details but based on their intuition and experience.

As a result of certain shortcomings during construction, there have been a number of associated building failures that may or may not be attributed to the type of scaffolding employed in building construction.

On a general note, column buckling is the only associated deficiency of any scaffolding materials that may eventually contribute to a partial or total collapse of a building system. Column bulking is considered to be one of the critical modes of failure in bamboo scaffolds (Yu *et al.*, 2003), which often leads to their overall collapse. Unfortunately, outside Hong Kong and in many developing nations like Nigeria, there is currently no regulation of the bamboo scaffolding trade, opening doors to all forms of quackery and of course frequent fatal accidents and rampant failure of structures under construction. Failure of poorly erected bamboo scaffolding in Nigeria, though rarely researched or properly investigated, remains one of the significant causes of structural collapse, thereby propping up the nation's construction industry as one of the most dangerous in the world. Scene of some of the building collapse sites in Nigeria is displayed in Fig. 7. The failure in buildings was insinuated to be due to improper scaffolding systems.

Tubular steel scaffolds usually don't fail due to column buckling, except if they have been used beyond specification limits. Such limits include general preservation procedures, aging, and loading specifications.

Apart from column buckling, the effect of high wind is another factor that often leads to the failure of scaffolding systems. A typical failure scene of scaffolding, which was due to high wind, is shown in Fig. 8.

Safety Challenges of Scaffolding Systems

Safety of scaffolding will depend on how it is assembled, though it is obvious that steel has a definite advantage due to regular shape, trusted fabrication process of steel tubes in the factory with all the accessories, such as collars, T-joints, etc., fabricated to fixed sizes. A steel tube can be clamped into the end of a collar by a bolt that bears directly onto it. Bamboo, on the other hand, has

Fig. 8 Failure in building due to tubular steel collapse. Reproduced from Booth, S., 2017. Scaffolding collapses at Croydon building site during high winds. Available at: <http://www.croydonadvertiser.co.uk/scaffolding-collapses-at-croydon-building-site-in-high-winds/story-30158667-detail/story.html> (accessed 01.06.17).

inherent size variability with anisotropic behavior and a bolt bearing onto it can cause it to splinter and split. This requires more care and effort in adapting bamboo to stable scaffolds. Bamboo scaffolds stand a risk of being brought down more easily by high winds and turned at lethal speeds to spears.

Cost Variation of Scaffolding Materials

Cost effectiveness of construction materials, among other building expenses, is usually given due focus in a construction project. Building owners, constructors, and other stakeholders in the built environment give cost of construction a priority, after safety considerations have been made.

Attempts made to compare the price of a typical piece of bamboo in comparison with tubular steel scaffold has shown that it is only about 6% the cost of a similar length of a steel scaffolding (Jiang, 2008). It is obvious that the key reason why bamboo is selected for scaffolding in certain developed countries is due to this wide variation in cost. Generally, considering total cost of bamboo with steel scaffold in a large building, bamboo is considerably cheaper than tubular steel scaffolding system.

In a complete analysis of scaffolding requirements for a seven story building, Jiang (2008) compared the cost of bamboo to tubular steel. The analysis has shown that bamboo scaffolding could save about \$20,000 over steel scaffolding requirements in the same building. In other words using bamboo scaffolds would save close to \$5.91 per square meter of the building. Consequently, when cost is a major concern, then using bamboo scaffolds can be extremely advantageous.

Summary and Conclusions

In this article, various pros and cons that are associated with the use of either bamboo or tubular steel scaffolding for building construction have been explored. From the two materials, bamboo has been the most innovative patented scaffolding system so far around the world (Poon, 2007), at the rate of 60% bamboo and 40% steel. The choice of bamboo scaffold for construction dwells entirely on its availability and accessibility, and ultimately the cost. Bamboo is a renewable resource; it is easy and quicker to assemble, as it is tied with strong material straps at the joints; and the design is simple and repetitive. The poles, beams, or cross braces of bamboo can be utilized for up to 7 years, after which it can still be cut into material for making walk boards, finally ending up as a firewood on site once the walk boards are damaged.

On the other hand, tubular steel scaffolds are mostly used in developed nations, but often imported to other developing countries. There are standard technical details for using steel scaffolds, which makes it the more preferred all over the globe. Bamboo is much cheaper when compared with tubular steel scaffolds; however, there are more safety concerns associated

with bamboo scaffolds. Steel scaffold has locks and pins to ensure good connection where bamboo does not. With bamboo the connection points are tied straps that can be subject to wear and loosening.

In case of steel scaffolds, there are accessories, such as wheels and ladders, that fasten securely to the frame system. Also, the walk boards are hooked on securely as well. However, with bamboo scaffolds, the walk board RESM-S are just laid unfastened on the cross beams and ladders.

Steel scaffold can be engineered and tested for height and load capabilities. Steel scaffold members don't have an age limit like bamboo does. There is no way to know for sure how old the poles and cross braces are. I did not see any date stamps on them in my inspections.

It is also interesting to note that steel scaffold is as recyclable as bamboo. It can be melted and its by-products are used to make asphalt.

Biogas Production From Solid Waste Landfill

Ivan FS Santos, Regina M Barros, and Geraldo L Tiago Filho, Federal University of Itajubá (UNIFEI - MG), Itajubá, Brazil

© 2020 Elsevier Inc. All rights reserved.

Introduction

The generation of waste in a region tends to rise with its economic growth. One of the options less costly and more used throughout the world for the disposal of urban solid waste are the landfills. These landfills are widely used in developing countries and consist of large anaerobic reactors where the input of solid waste and the output of biogas and slurry. The biogas is produced by anaerobic digestion of organic matter and has high energy potential (due to its high percentage of methane) and therefore can be used in various applications such as heat generation, electricity or production of fuel for vehicles. The energy use of biogas from landfill contributes to the reduction of environmental impacts of this structure because it employs the best land used for the construction of the landfill and reduces the emission of greenhouse gases into the atmosphere. These benefits are due either by reducing emissions of methane in the landfill or by energy production with lower carbon emissions from fossil fuels.

Municipal Solid Waste

Increasing industrial production, population growth and urbanization have increased the consumption of goods and services. This has resulted in increased solid waste generation, specifically in urban areas, in which waste includes public and household solid waste and is called municipal solid waste (MSW) (Barros *et al.*, 2014). This growth can be seen in the projections presented by Hoornweg and Bhada-Tata (2012), which predicted urban solid waste generation growth, from 1.3 billion tonnes/year in 2012 to approximately 2.2 billion tonnes/year in 2025. This makes MSW management one of the greatest challenges faced by most developing countries (Chhabra *et al.*, 2016).

According to estimates by Hoornweg and Bhada-Tata (2012), 44% of all waste is generated in the 34 developed countries participating in the OECD. The average MSW generation rate in these countries is around 2.2 kg per inhabitant per day, which contrasts with average values of 0.65 kg per inhabitant per day of underdeveloped and developing countries of the African continent. Therefore, waste generation is related to each population's economic power as a country or region and, as each group develops economically, it will have to invest more intensely in appropriate waste treatment.

Sanitary Landfills

Sanitary landfills are an improvement of one of the oldest techniques used by humankind to dispose of solid waste generated by anthropic activities. Nowadays, engineering leads the way in restricting solid wastes to a minimum space, ideally causing the smallest amount of damage to the environment or public health. This technique is carried out through solid waste compacting in the soil in the form of layers that are periodically covered with dirt or other inert materials (Environmental Protection Agency of the State of São Paulo – CETESB, 2018). This method is usually chosen by developing countries because of its lower costs. However, many developed countries still employ landfills as an integral part of their solid waste management infrastructure (as noted by Cuartas *et al.*, 2018).

According to the US Environmental Protection Agency (USEPA, 2018) US federal law (revised 09/2018) places the following requirements for construction of MSW landfills:

- (1) Fulfillment of location restrictions: Set distances from wetlands and plains, among other landforms;
- (2) Use of geomembranes to cover the sides and back of the landfill;
- (3) Slurry collection and removal systems for further treatment and disposal;
- (4) Groundwater quality monitoring systems;
- (5) Criteria for landfill coverage and care after closure;
- (6) Corrective action devices for control and treatment of the landfill and nearby groundwater;
- (7) Guarantee of financial security for environmental protection during and after landfill closure.

The ISWA (2010) states that a complete and regular application of soil coverage on the landfill is a fundamental control mechanism for effective management of a modern and well-designed landfill. This coverage can be done using inert materials (various types of soils), artificial or synthetic materials (geotextile blankets or plastic films) or even by means of reuse of materials present in the waste (wood or shredded plastics).

Also according to ISWA (2010), ease of application is a factor that needs to be considered when choosing the daily coverage for use on any given site. When selecting natural soil coverage, dry and brittle soils should be considered easier to handle than damp clays. However, each type of soil has advantages and disadvantages and the reality is that most landfills tend to use the material that is available in the most feasible form.

Table 1 Advantages and disadvantages to landfill usage. Elaborated by the authors based on Cheremisinoff, Tansel *et al.* and Kalyany and Pandey

Advantages	Disadvantages
Lower disposal costs	Older sites built before leachate collection and gas production are now sources of difficult-to-control pollution
Alternative that can be used for a wide variety of wastes	Risk of soil and groundwater contamination
Often found as the only final disposal route for wastes from other MSW management options such as incineration	Decrease in available areas near urban centers
The gas produced in the landfill can be used for thermal and electric energy generation	Landfills reach a lower waste conversion rate for energy than other or MSW management options
Restored land can provide valuable space for wildlife habitat or for leisure	The convenience of landfills tends to discourage the development of innovative waste management strategies
Waste decomposes in the soil, which leads to the replacement of valuable natural resources	Explosion hazards in cases of gas leakage
No need for skilled labor	Leakage costs
Use of the available area upon closing the power plant for implantation of photovoltaic panels	The landfill causes sound pollution, odors and, the frequent traffic of heavy vehicles, increasing problems related to regional air pollution

Renewable and Sustainable Energy Reviews 31, 113–120. doi:10.1016/j.rser.2013.11.020.

Municipal Solid Waste disposal costs in landfills vary between 10 and 30 USD t⁻¹ for low-income countries and between 40 and 100 USD t⁻¹ for high-income countries (Hoornweg and Bhada-Tata, 2012).

The advantages and disadvantages of the use of landfills are described in Table 1.

Biogas Production in Sanitary Landfills

The production of biogas in landfills occurs through anaerobic digestion. According to Leonzio (2016), biogas composition is approximately 55%–70% methane (CH₄) by volume; 30%–45% carbon dioxide (CO₂); 80–100 ppmV ammonia (NH₃), 1000–3000 ppmV hydrogen sulfide (H₂S) and other hydrocarbons (<100 ppmV). Traces of siloxines can also be found.

Upon introducing MSW into the landfill, the organic components begin to undergo a series of chemical reactions. In the presence of atmospheric air near the landfill surface, natural organic components are oxidized aerobically, producing CO₂ and H₂O. However, the main reaction in landfills is anaerobic digestion. This occurs in three main stages (according to Themelis and Ulloa, 2006).

- (1) Fermentative bacteria perform hydrolysis of complex organic matter in soluble molecules;
- (2) These molecules are converted into simple organic acids, CO₂ and H₂ by acid-producing bacteria. The main acids produced are: Acetic acid (CH₃COOH), propionic, butyl and ethanol;
- (3) Fermentative bacteria carry out hydrolysis of complex organic matter, transforming it into soluble molecules;
- (4) These molecules are converted into simple organic acids, CO₂ and H₂ through acid producing bacteria. The main acids produced are: acetic acid (CH₃COOH), propionic, butyl and ethanol;
- (5) Finally, CH₄ is formed by methanogenic bacteria, both by breaking down these acids in CH₄ and CO₂ (Eq. 1) and by the reduction of CO₂ by H₂ (Eq. 2) (Themelis and Ulloa, 2006).

Landfill gas production passes through four phases listed by Farquhar and Rovers (1973) as described below. All phases are shown in Fig. 1.

- Phase I – First aerobic phase: Aerobic decomposition occurs with oxygen consumption present in the waste at the time of disposal. At this stage the production of CO₂ is verified.
- Phase II – Non-methanogenic anaerobic: Anaerobic activity becomes predominant. During this period, a peak occurs in the concentration of carbon dioxide and hydrogen production is relevant. At this stage, there is still the substitution of N₂, which can, however, be reproduced in smaller quantities by means of denitrification.
- Phase III – Unstable methanogenic anaerobic: An increase is seen in CH₄ concentration and stabilization at a very high value. At this stage, the concentrations of CO₂ and N₂ are reduced to final concentrations.

Fig. 1 Variation of gas composition produced in landfills throughout the various phases of microbiological activity. Source: Farquhar, G.F., Rovers, F.A., 1973. Gas production during refuse decomposition. *Water, Air, Soil and Pollution*. 2, 483–495. doi:10.1007/BF00585092.

Fig. 2 Biogas processing path through anaerobic digestion in landfills. Reproduced from Lee, U., Han, J., Wang, M., 2017. Evaluation of landfill gas emissions from municipal solid waste landfills for the life-cycle analysis of waste-to-energy pathways. *Journal of Cleaner Production* 166, 335–342. doi:10.1016/j.jclepro.2017.08.016.

- Phase IV – Stable methanogenic anaerobic: At this stage, gas composition and production rates reach constant levels. This does not exclude the occurrence of abrupt variations in gas production due to changes in environmental conditions, nor long-term variations caused by nutrient depletion.

Fig. 2 Summarizes all possible landfill gas emissions (obtained in Lee *et al.*, 2017). See below:

- (1) CO₂ emission due to the combustion of captured CH₄;
- (2) CH₄ uncaptured emissions;
- (3) CO₂ emissions due to the oxidation of CH₄ as it passes through the landfill cover layer;
- (4) CO₂ emissions due to waste decomposition.

Methane must be captured and conducted using collection devices, as shown in Fig. 2. When not used, this gas must always be burnt to convert to CO₂, a gas with a much lower global warming potential.

There are many potential biogas applications for landfills. Chen *et al.* (2010) cites landfill biogas applications which are already in place in China including: Power generation in internal combustion engines; power generation in Stirling engines; the production of steam and heated water in gas boilers; production of vehicular fuel after enrichment to increase the content of CH₄; use as an auxiliary fuel in furnaces and incinerators; for treatment of landfill leachate via combustion and evaporation

and for flushing of hospital waste. Biogas can also be used to produce other chemicals such as methanol, gasoline, and even hydrogen (Yang *et al.*, 2014) in domestic stoves (not necessarily with the same yield, as shown by Grima-Olmedo *et al.* (2014) and even for the supply of desalination plants (Silva *et al.*, 2018).

Estimation Models for Biogas Production in Sanitary Landfills

The equations for estimation of gas production in sanitary landfills are generally based on first-order kinetic reactions, such as those seen in Eq. 3, used in LandGEM® software developed by the US Environmental Protection Agency (USEPA, 2005), and Eq. 4 presented by IPCC (1996).

$$Q = \sum_{i=1}^n \sum_{j=0,1}^1 k \cdot L_0 \cdot \left(\frac{M_i}{10}\right) \cdot e^{-kt_{ij}} \quad (3)$$

$$Q = L_0 \cdot R(e^{-kc} - e^{-kt}) \quad (4)$$

Where: k = decay rate for methane production in y^{-1} , L_0 = Methane gas generation potential $m^3 t^{-1}$, M_i = residual mass in the landfill in year i in t (USEPA, 2005), Q = annual methane flow in $m^3 y^{-1}$, R = residue flow per year in $t y^{-1}$, c = landfill useful life and t = time since the landfill's opening (IPCC, 1996).

Methane generation potential L_0 refers to the total amount of methane that could be produced per one ton of solid waste. This parameter is almost entirely dependent on the type of waste in the landfill. Table 2 presents L_0 values suggested by Conestoga-Rovers & Associates (2004), depending on the type of waste.

Climatic aspects such as precipitation and temperature are among the factors that influence the constant methane production rate (k) in a landfill, which has been studied by several authors. The k values obtained in the literature are highly variable, ranging from 0.02 (in arid areas) to 0.7 (in wet bioreactors, according to USEPA, 2005). Ishii and Furuichi (2013) obtained values of 0.05 and $0.062 y^{-1}$ for paper and food waste for the region of Hokkaido, Japan (cold weather region). Maciel and Jucá (2011), by means of an adjustment of the experimental data to simulation data using the LandGem software, obtained a value of k equal to $0.8 y^{-1}$ in an experimental cell of a landfill in the state of Pernambuco, Brazil. Amini *et al.* (2012) studied landfills in Florida (American region with high summer temperatures) and obtained k values ranging from 0.04 to $0.131 y^{-1}$. Table 3 presents the suggestions of the k values given by the Conestoga-Rovers & Associates (2004).

Another estimate which involves a mass balance considering degradable organic carbon can also be found in IPCC (1996), as presented in Eq. 5.

$$Q_{CH_4} \left[\frac{ton}{ano} \right] = MSW_T \cdot MSW_f \cdot MCF \cdot DOC \cdot DOC_F \cdot F \cdot \left(\frac{16}{12} \right) \cdot (1 - OX) \quad (5)$$

Table 2 Suggested Values for L_0

USW Category	Minimum value for $L_0 \text{ m}^3 \text{ t}^{-1}$	Maximum value for $L_0 \text{ m}^3 \text{ t}^{-1}$
Relatively Inert	5	25
Highly Degradable	140	200
Altamente degradável	225	300

(License: CC BY 3.0 IGO).

Table 3 Suggested values for k in y^{-1}

Annual Precipitation in mm	Relatively inert	Moderately degradable	Highly degradable
< 250	0.01	0.02	0.03
250–500	0.01	0.03	0.05
500–1000	0.02	0.05	0.08
> 1000	0.02	0.06	0.09

Source: Conestoga-Rovers & Associates, 2004. Handbook for the Preparation of Landfill Gas to Energy Projects in Latin America and the Caribbean. Energy Sector Management Assistance Programme paper series. World Bank, Washington, DC. © World Bank. Available at: <https://openknowledge.worldbank.org/handle/10986/18081>. (License: CC BY 3.0 IGO). Cuartas, M., López, A., Pérez, F., Lobo, A., 2018. Analysis of landfill design variables based on scientific computing. Waste Management 71, 287–300. doi:10.1016/j.wasman.2017.10.043.

Where MSW_T = Total waste generated annually in tonnes, MSW_f = fraction of solid waste sent to the landfill, MCF = Methane correction factor, DOC = Degradable organic carbon fraction, DOC_f = Degraded DOC fraction, F = Methane fraction in biogas and OX = the oxidation fraction of methane (Generally equal to 0) (IPCC, 1996).

The methane correction factor (MCF) is related to the type of landfill operation and can be obtained through the use of Table 4; these data are provided by the IPCC (1996). The fraction of degradable organic carbon (DOC) is based on the composition of the residue and can be obtained through Eq. 6. The fraction of this carbon converted to biogas (DOC_f) can be obtained by means of Eq. 7 (IPCC, 1996).

$$DOC = 0,4.A + 0,17.B + 0,15.C + 0,3.D \quad (6)$$

$$DOC_f = 0,014T + 0,28 \quad (7)$$

Where: A = Percentage of paper and textile material in the waste; B = Percentage of pruning waste, gardening or other organic putrescible material other than leftover food; C = Percentage of food debris, D = Percentage of wood or straw and T = Temperature ($^{\circ}\text{C}$). Variables A, B, C, D can be obtained through analysis of gravimetric composition of the city or region where the landfill will be implanted. This composition varies from region to region. Table 5 shows the differences in the gravimetric composition of solid waste between South, Central and North America. In it, it is possible to observe that when economic conditions increase, organic material in MSW reduces.

Other estimates can be found in the literature. Das *et al.* (2016) presented a first order multiphase model developed by the Agricultural University of Wageningen which considers eight different types of waste with three types of degradation rates which are differentiated by index i, according to Eq. 8.

$$Q = \varepsilon \cdot \sum_{i=1}^3 c \cdot MSW_T \cdot C_0 \cdot k_{1,i} \cdot e^{-k_{1,i} \cdot t} \quad (8)$$

Where: ε = Dissimilation factor; i = Fraction of the residue degradation rate of $k_{1,i}$; c = Biogas conversion factor per kg of degraded C; MSW_T = Residue mass, in t; C_0 = Concentration of organic carbon in the residue in KgC t^{-1} residue, k_1 = Rate of degradation of the residues in y^{-1} , t = Time in y, i = Index of each type of residue (varying between 1 and 3, since this model adopts 3 degradation rates) and Q = Biogas flow in $\text{m}^3 \text{y}^{-1}$.

Table 4 Landfill classification and MCF parameter determination

Type of sanitary landfill	MCF
Controlled	1
Uncontrolled – Deep (>5 m)	0,8
Uncontrolled – Shallow (<5 m)	0,4
Unclassified Landfills – Default Value	0,6

A specific model for the Indian reality as a function of temperature was developed by Kumar *et al.* (2016), described in Eq. 9. According to the authors, this model can be used by local authorities to plan methane recovery in sanitary landfills.

$$CH_4 = \alpha (MSW_T)^{0.179} \cdot e^{0.0069 \cdot T + E} \quad (9)$$

Where: CH_4 = Methane flow rate; MSW_T = Total mass of waste per year per ton; α = Model parameter (estimated at 2.33, varying between 0.8 and 7.05); E = Error associated with the model; and T = Temperature in °C (Kumar *et al.*, 2016).

The uncertainties related to landfill gas generation is the greatest difficulty in estimating the gas flow rate collected there and its eventual use for energy generation (Amini *et al.*, 2012). Since first-order models are extremely dependent on their input parameters, they must be carefully chosen to ensure the model's effectiveness. Factors such as precipitation, mean temperature and residue composition can be used to aid in the selection of these parameters. A detailed comparison with rich discussions among several methods of prediction of biogas production in landfills can be obtained in Scharff and Jacobs (2006).

Biogas Utilization in Sanitary Landfills for Electrical Energy Generation

Biogas produced in landfills can be considered a renewable fuel and stands out as an excellent energy generator, by contributing to distributed generation. In this form of generation, energy is produced close to consumer centers, reducing the risks and losses which can be characteristic of the centralized generation of extensive transmission lines. As the results of Leme *et al.* (2014) show, environmental performance of landfills performs better on issues such as global warming emission reductions, ozone layer depletion, human toxicity, acidification and abiotic depletion, when using biogas from this type of electrical generation.

The power levels, P_{el} and energy, E , which can be generated each year through energy conversion of the biogas is calculated using Eqs. 9 and 10.

$$P_{el} = Q \cdot LHV \cdot \eta \cdot E_c / 1000 \quad (10)$$

$$E = P_{el} \cdot 8,760 \cdot C_F \quad (11)$$

Where: P_{el} = Electric power in kW; Q = Biogas flow to be used in $m^3 s^{-1}$; η = Energy conversion efficiency; E_c = Landfill gas collection efficiency; LHV = Lower calorific value of biogas = $22 \times 10^6 J m^{-3}$ (Guerini Filho *et al.*, 2018); 8760 = Number of hours per year; C_F = Capacity factor; E = Energy available annually in $kWh y^{-1}$.

The E_c value varies with the characteristics of the landfill. The value suggested by USEPA (2005) is 75%, while used a value of 55.5%. A representative schematic of a biogas plant installed in a landfill is presented in Fig. 3. As shown in the figure, the components required for the plant are:

- (1) Gas collection drains;
- (2) Piping to transport the collected gas;

Fig. 3 Diagram of electrical energy power plant in a sanitary landfill. Adapted from Santos, I.F.S., Barros, R.M., Tiago Filho, G.L., 2018a. Economic study on LFG energy projects in function of the number of generators. Sustainable Cities and Society 41, 587–600. doi:10.1016/j.scs.2018.04.029.

- (3) Combustion burner for unused biogas;
- (4) Gasometer for storage and gas flow control;
- (5) Gas treatment unit, which can be dispensed at the cost of further damage to energy conversion technology;
- (6) Compressor for pumping and raising gas pressure;
- (7) Energy conversion unit for the conversion of the biogas chemical energy into mechanical energy. **Table 6** shows a comparison of the yields and emissions associated to the two main biogas energy conversion technologies of landfills; and finally
- (8) Electric generator for conversion into electric energy.

The costs of a biogas-fueled thermoelectric plant can be estimated using aggregate cost, which are given in terms of installed power. **Table 7** presents estimates in the literature that can be used to plan the energetic use of landfill biogas and for economic viability analyzes.

Chen et al. (2010) cite some of the problems commonly encountered in landfills in China: (i) Gas collection is less than estimates (due to errors in estimates or structural problems); (ii) problems with gas emission limits; and (iii) wear and tear

Table 6 Characteristics of the energy conversion technologies in sanitary landfills. Obtained in Bove and Lunghi

Technology	NO_x Emissions $\mu g\ kJ^{-1}$	Electrical energy yield with generator	CO emissions $\mu g\ kJ^{-1}$
Internal combustion engines	56.6	33%	56.6
Gas turbines	15	28%	19

Note: Obtained Bove, R., Lunghi, P., 2006. Electric power generation from landfill gas using traditional and innovative Technologies. *Energy Conversion and Management* 47, 1391–1401. doi:10.1016/j.enconman.2005.08.017.

Table 7 Estimates of the costs of electricity generation from landfill gas present in the literature

Description	Equation
Capital, operation and maintenance costs estimate.	$I = 11,550.P^{0.78}$ (12)
Considers a plant operating 8000 h per year with an electrical efficiency conversion of 33%. Presented by Gómez et al. (2010)	$C_{om} = 115.P$ (13)
	Where: I = Capital cost, in €; P = power, in kW; and C_{OM} = operation & maintenance cost, in $€\ y^{-1}$
Aggregate estimate developed by Santos et al. (2015) without considering gas treatment using data of Brazilian reality. Given as a function of electrical power and efficiency of the adopted conversion technology	$I = \beta.P + 0.52$ (14)
	Where: I = Capital cost, in 10^6 USD; P = power, in kW; and β = constant given depending on the efficiency conversion technology. For the Brazilian internal combustion engines $\beta_{ICE} = 0.008$; and for gas turbines $\beta_{GMT} = 0.012$
Estimate presented by USEPA (2016)^a of a complete co-generation plant using reciprocating engine. Includes gas treatment (dehydration equipment and filtration). Gross capacity factor of 93%	$I = 1.900.P + 250,000 + 355.P + 63.L + 106.\lambda + 12,000$ (15)
	Where: I = Capital cost, in USD; P = Power, in kW; 250,000 = Connecting cost to the grid system; L = Piping length, in ft; λ = Trench for the steam piping length, in ft; and 12,000 = Recirculating pump cost.
Estimate presented by USEPA (2016) of a complete co-generation plant using gas turbine. Includes gas treatment (dehydration equipment, siloxane absorbers, and filtration). Gross capacity factor of 93%	$I = 2,340.P - 0.103.P^2 + 250,000 + 355.P + 63.L + 106.\lambda + 12,000$ (16)
	Where: I = Capital cost, in USD; P = power, in kW; 250,000 = Connecting cost to the grid system; L = Piping length, in ft; λ = Trench for the steam piping length, in ft; and 12,000 = Recirculating pump cost.

^aMore information about these costs can be found in **USEPA (2016)**.

Table 8 Energy potential of biogas through municipal solid waste in multiple countries

Country	Energy potential	Reference
Mexico	Theoretic Potential: 30.2 TWh y^{-1} Economically viable potential: 1.1 TWh y^{-1}	(Rios and Kaltschmitt, 2016)
Uruguay	30–45 GWh y^{-1} of electrical energy and 108–162 TJ y^{-1} of heat	(Moreda, 2016)
Brazil	Between 6.9 and 11.8 TWh y^{-1}	(Santos et al., 2018b)
Serbia	49.72 Mtoe y^{-1} (equal to 578.24 GWh y^{-1})	(Cvetković et al., 2014)
Urban Regions of Africa	62.5 TWh in 2012 and 122.2 TWh in 2025	(Scarlát et al., 2015)
Poland	82 million $m^3\ y^{-1}$ just in organic material, equal to 115 GWh y^{-1}	(Igliński et al., 2015)
Turkey	4.85 TWh y^{-1}	(Ozcan et al., 2015)
China	418.5 MW in the case of installation in all sanitary landfills (2010) for the generation of energy	(Chen et al., 2010)
Spain	Electrical energy potential 4.02 TWh y^{-1}	(Gómez et al., 2010)

on the combustion engines due to impurities present in the biogas which make gas treatment necessary. Despite these difficulties, the use of biogas improves the environmental impact of landfills and has a very high potential for worldwide application.

Table 8 Presents data on the energy potential that can be obtained through municipal solid waste biogas in several countries available in the literature.

Conclusion

Economic and population growth have paved the way for growing rates of waste generation. Inadequate and uncontrolled waste disposal generates significant impacts on the environment, such as greenhouse gas emissions, soil contamination and water sources (surface and groundwater).

Landfills, while having drawbacks in some respects, are still widely used for the disposal of municipal solid waste in developing countries and are still an essential part of waste management in developed countries. In sanitary landfills the decomposition of organic matter in anaerobic environment generates biogas. This gas has several applications, such as the generation of heat, electric energy and the production of vehicular fuels. Among the difficulties in the application of this gas are the correct prediction of the gas collected and the presence of impurities in its composition.

Great potential lies in electric energy generation from biogas in several countries. When harnessed, this significantly improves the environmental performance of landfills and reduces the energy liabilities of the goods and products that generated the waste sent to the landfill.

Introduction

In recent years, the benefits of biopolymer research and biopolymer-based composites (predominantly derived from proteins and polysaccharides) have attracted considerable attention for use in medical applications. The usage of biopolymer-based composites is increasing considerably owing to their high biocompatibility, optimal mechanical properties, ease of availability from natural sources, low immunogenicity, non-mutagenic, non-carcinogenic, and non-irritating properties, hemocompatible nature, biodegradable and edible nature, and ability to adsorb bioactive molecules (Jacob *et al.*, 2018). Biopolymers are successfully applied in various medical applications due to their biomimetic functions, which are similar to native extracellular matrix (ECM) systems (Velema and Kaplan, 2006). Biopolymer-based biocomposite materials are prepared using the beneficial features of two or more different biopolymers while maintaining their unique physicochemical properties to improve positive outcomes for medical applications (Dhillip Kumar *et al.*, 2018b). Biopolymer-based composites provide numerous advantages in medical applications such as the ability to act as a carrier molecule for targeted delivery of bioactive compounds, high level of biocompatibility within tissues, cells and cell compartments, good degradation kinetics and efficient antibacterial activity (Nitta and Numata, 2013; Nguyen *et al.*, 2013).

The physicochemical properties of biopolymers such as structure, morphology, solubility, tensile strength, chemistry modification with suitable molecules, and biomimicry of the ECM aids to control the mechanical properties of biopolymer-based products such as scaffolds, tubes, porous sponges, electrospun fibers, sponges, films, sheets, microbeads, membranes, dressing materials, microcapsules and hydrogels. The schematic illustration of various forms of biopolymer-based composites are given in Fig. 1.

This article is organized into five different sections. Section "Introduction" deals with an introduction of the biopolymer-based composites and their medical applications in brief. Section "Types of Biopolymers Derived from Natural Sources" describes the different types and sources of biopolymers and their functional role in medical applications. In Section "Biopolymer-Based Composites for Medical Applications", biopolymer-based composites and their application in tissue engineering, medical implants, drug delivery and wound healing is discussed in detail. Section "Fabrication Methodology of Biopolymer-based Composite" explains the different methodology available to fabricate biopolymer-based composites for medical applications, and finally in Section "Clinical Application and Major Global Clinical Trial Status of Biopolymers in Medical Applications" clinical applications and major global clinical trial status of biopolymers in medical applications are given.

Types of Biopolymers Derived From Natural Sources

There are several types of biopolymers derived from natural sources which have been widely prepared and used as a functional biomaterial for different medical applications. They are predominantly derived from proteins and polysaccharides which include collagen, gelatin, silk fibroin, keratin, natural rubber latex, chitin and chitosan, starch and its derivatives, pullulan, alginate, cellulose and its derivatives, albumin, casein, hyaluronic acid, chondroitin sulfate, laminarin, fucoidan, sargassum, carrageenan, agar, ulvan, dextrans, levan, curdlan, arabic gum, kondagogu gum, tragacanth gum, xanthan gum, gellan gum, and guar gum. Detailed information on different types and sources of biopolymers and their functional role in medical applications are listed in Table 1.

Biopolymer-Based Composites for Medical Applications

Tissue Engineering

Tissue engineering combined with biopolymer-based composites offers a promising approach for the treatment of damaged cartilage and bone tissues (Moreira *et al.*, 2018). Biopolymer-based nanoparticles has successfully been used to deliver drugs and genes to achieve good therapeutic efficiency in tissue engineering (Nitta and Numata, 2013). Kaczmarek *et al.* (2018) prepared a novel 3D porous scaffold (chitosan, collagen and hyaluronic acid) through the lyophilization process for tissue engineering and regenerative medicine. The scaffolds showed good mechanical properties, and thermal stability, as well as enhanced cellular adhesion with increased proliferation rate of osteosarcoma SaOS-2 cells (Kaczmarek *et al.*, 2018). A silk fibroin based bilayer nanobiocomposite scaffold showed excellent biocompatibility, good hydrophilicity, and superior osteogenic potential with cord blood derived mesenchymal stem cells, and it has been developed as a potential graft for bone tissue for clinical applications (Singh and Pramanik, 2017). Hyaluronic acid (oxidized) functionalized gelatin microcarriers were tested in both *in vitro* and *in vivo*

Fig. 1 Schematic illustration of various forms of biopolymer-based composites used for medical applications.

models, and the test material showed a high level of viability with all types of corneal cells (epithelial, stromal and endothelial). It can potentially be used for the development of microcarriers for applications in tissue engineering (Lai and Ma, 2017).

Medical Implants

In general, implantable devices or biomimetic devices are used to replace a damaged organ or structure to facilitate the normal function in the body. Heart, bones, eyes, ears, knees, breasts, hips and cardiovascular system implants are considered the most used implants in medical applications (Rebelo *et al.*, 2017). Some of the well-known advantages associated with biopolymers make this material more feasible for the preparation of biopolymer-based implants. Gelatin, chitosan polyurethane based electrospun materials showed exceptional biocompatibility and cell retention ability, and it can be used in implants for heart valves (Wong *et al.*, 2010). Chitosan, gelatin based composite films showed an improved water absorption and solute permeability rate. It is a transparent and flexible film and can potentially be used for contact lenses (Xin-yuan and Tian-wei, 2004). In another study, chitosan and gelatin blends were cross-linked with genipin and the optimized concentration of the blends showed good cell adhesion and proliferation properties with neuroblastoma cells. This material can be used in the field of nerve regeneration (Chiono *et al.*, 2008).

Drug Delivery Systems

Biopolymer-based composites show numerous advantages in drug delivery owing to their biocompatibility and biodegradability. They function as an excellent carrier molecule for both hydrophilic and hydrophobic drugs in order to achieve sustained drug release. These biopolymers have been shown to possess excellent biocompatibility, hemocompatibility, stability in physiological conditions and are non-immunogenic, they are also considered as a safe material in drug delivery systems. The complexity and structure of the biopolymer facilitates to protect the nativity of the drug and improve their stability in biological conditions. The surface chemistry of biopolymers can be functionalized with specific ligands to achieve targeted drug delivery (Sundar *et al.*, 2016). Hyaluronic acid functionalized gold nanoparticles were conjugated with the drug metformin to target CD44 receptors in HepG2 cells for the treatment of liver cancer (Kumar *et al.*, 2015). Kondagogu gum capped gold nanoparticles were synthesized using sunlight mediated green synthesis; here the anionic polysaccharide based kondagogu gum acted as a reducing, stabilizing and

Table 1 Types, sources, functional role and medical applications of biopolymers

Types of biopolymer	Sources	Functional properties	Various forms of biopolymer in medical applications	References
Collagen	Animals (e.g., fish)	Collagen based materials act as a good carrier molecule and helps to extend the shelf-life of the products	Scaffolds, sheets, tubes, sponges, films, membranes, and composites	(Bhagwat and Dandge, 2018)
Gelatin	Derived from hydrolysis of collagen	It exhibits both positively and negatively charged amino acids, and it facilitates surface modification of gelatin with new functional materials	Microcapsules, microspheres, sealant for vascular prostheses, absorbent pads and dressings	(Han and Lv, 2018)
Silk fibroin	<i>Bombyx mori</i>	It has been integrated with different materials via chemical modification	Films, gels, membranes, powders, porous sponges, wound dressings, matrices, prostheses and implants	(Kim <i>et al.</i> , 2015)
Keratin	Epidermal skin, hair, nails, bird feathers and mammalian hooves	It is a fibrous protein and possesses high physical and chemical stability due to their disulphide bonds	Hydrogels, films, and biomaterials	(Mori and Hara, 2018)
Natural rubber latex	<i>Hevea brasiliensis</i>	It aids to stimulate different cellular processes which includes adhesion, formation of ECM, and promotion of tissue regeneration	Dermal wound dressing materials	(Dhilip Kumar <i>et al.</i> , 2018b; Wattanakaroon <i>et al.</i> , 2017)
Chitin and Chitosan	Animals (e.g., shrimps, crabs)	Chitin and chitosan based biomaterials possess unique properties including hemostatic, solubility, antioxidant, and antibacterial	Wound dressings, coatings (antibacterial and stent), scaffolds, membranes, sensors, carrier molecules, and nanomaterials	(Usman <i>et al.</i> , 2016)
Starch and its derivatives	Plants (stem, tuberous tissues, seeds) and algae	It is composed of glucose units and is semicrystalline in nature	Fibers, films, powders, hydrogels, and sponges	(Hemamalini and Dev, 2018)
Pullulan	Extracellular microbial polysaccharide (<i>Aureobasidium pullulans</i>)	It is highly soluble in water and exhibits very good structural flexibility	Capsules, gels, films, and nanoparticles	(Han and Lv, 2018)
Alginate	Algae	Acts as scaffolds for cell growth in tissue engineering	Hydrogels, microbeads, fibers, and nanomaterials	(Wongkanya <i>et al.</i> , 2017)
Cellulose and its derivatives	Plants (cotton, oat husk, sugarcane bagasse, and peels of bananas, and oranges) and microorganisms (bacteria)	It is a water-insoluble, stable, fibrous polysaccharide. Engineered cellulose aids excellent drug release properties	Hydrogels, and beads	(Gopinath <i>et al.</i> , 2018)
Albumin	Animals (bovine, rat chicken eggs, etc.)	The chemical modification of albumin is easy for drug delivery applications and it shows high binding capacity with different types of drugs	Nanostructures	(Karimi <i>et al.</i> , 2016)
Casein	Whole milk	It possesses a unique amphiphilic nature which contains both hydrophilic and hydrophobic ends. The amphiphilic surfaces has been employed in surface modification	Nanowhiskers, composites, and films	(Gu and Catchmark, 2013)
Hyaluronic acid (HA)	Animals (synovial fluid, vitreous body of the eye and umbilical tissue)	It is a linear polysaccharide and one of the essential components of the extracellular matrix, and HA-based medical products are clinically available for the past three decades	Hydrogels, matrix, films, scaffolds, electrospun fibers, non-woven meshes, sponges, sheets, and nanoparticulate fluids	(Burdick and Prestwich, 2011; Park <i>et al.</i> , 2017)
Chondroitin sulfate	Bovine trachea, and fish (shark)	Used as a therapeutic intervention for osteoarthritis and cartilage damage	Matrix	(Henrotin <i>et al.</i> , 2010)
Laminarin and Fucoidan	Brown seaweed	It aids certain biological functions, which includes the activation of immune cells, and enhances antiviral and antitumor responses	Solution	(Song <i>et al.</i> , 2017)
Sargassum	Brown macroalgae	It is identified as a nutritious seaweed and a rich source of different bioactive compounds. The extracted compounds are functionally used for various therapeutic applications	Medicinal food	(Yende <i>et al.</i> , 2014)

Table 1 Continued

Types of biopolymer	Sources	Functional properties	Various forms of biopolymer in medical applications	References
Carrageenan	Red algae	It is a sulphated polysaccharide and serves numerous applications in tissue engineering (bone, cartilage), wound healing, and drug delivery (antifungal, oral, nasal, ophthalmic, vaginal, and transdermal)	Different forms of hydrogels which include photocrosslinking hydrogels, gradient hydrogels, floating hydrogels, micropatterned hydrogels, hydrogel scaffolds, interpenetrating polymer network, nanogels, and bioinks	(Yegappan <i>et al.</i> , 2018)
Agar	<i>Gelidium cartilagineu</i> , <i>Gracilaria confervoides</i> or related red algae (Class Rhodophyceae)	It is a hydrophilic thermoreversible polysaccharide which acts as a stabilizer, and is widely used as a thickening, water holding and gel forming agent	Beads	(Yin <i>et al.</i> , 2018)
Ulvan	Green algae	It is a water-soluble sulphated polysaccharide and can be applied in both pharmaceutical and food industries	Biomaterials, wound dressings, and hydrogels	(Alves <i>et al.</i> , 2012)
Dextrans	Derived from bacteria	It is a homopolysaccharide and is extensively used as a coating material to improve the biocompatibility in biomedical and pharmaceutical applications	Scaffolds	(Sun and Mao, 2012)
Arabic gum	<i>Acacia senegal</i> and <i>Acacia seyal</i>	It is an edible gum that has the therapeutic efficacy to treat chronic kidney diseases, and is also used in the food industry	Due to their emulsifying, stabilizing, and binding properties, it has numerous applications in the food and medical industries	(Patel and Goyal, 2014)
Kondagogu Gum	<i>Cochlospermum gossypium</i> tree	It is an anionic polysaccharide from the bark and used as an additive material in the pharma industry	Reducing, capping and stabilizing agent for the production of gold and silver nanoparticles	(Dhilip Kumar <i>et al.</i> , 2018a)
Tragacanth gum	Bark of 15 different species of <i>Astragalus</i>	It is an anionic polysaccharide, with a high molecular weight and is soluble in water. It shows excellent structural stability under heat, acidity and long-term storage	Green synthesis of nanoparticles, nanofibers, hydrogels, burn wound dressings, and carrier molecules to achieve controlled release of drugs in drug delivery	(Ranjibar-Mohammadi <i>et al.</i> , 2013)
Xanthan gum	Derived from <i>Xanthomonas</i> bacteria	It is a high molecular weight exo-polysaccharide and is highly water-soluble. It shows a promising beneficial role in tissue engineering due to their shear-thinning and gelling behavior	Biomaterials, hydrogels, wound dressings, scaffolds, and synthesis of nanomaterials	(Kumar <i>et al.</i> , 2018)
Gellan gum	Derived from <i>Sphingomonas elodea</i> bacteria	It is an anionic linear expolysaccharide and has numerous applications in the pharmaceutical industry and medicine. Gellan gum is abundantly used to prepare oral, ophthalmic and nasal formulations	Oral formulations, capsules, beads, gels, granules, tablets, macrobeads, ophthalmic solutions, bioadhesives, and nasal gels	(Osmalek <i>et al.</i> , 2014)
Guar gum	Seeds of <i>Cyamopsis tetragonoloba</i>	It has a wide range of applications in different areas and facilitates surface chemistry functionalization	Nanocomposites, and films	(Auddy <i>et al.</i> , 2013)

capping agent for the production of gold nanoparticles. It facilitated the coupling of folic acid and fluorescein isothiocyanate on the surface of the gum in order to achieve better cellular imaging and folate receptor targeting efficiencies in MCF-7 cells (Dhilip Kumar *et al.*, 2018a).

Wound Healing

Biopolymers play a functional role in wound healing, and biopolymer-based composites are actively used for different types of wounds, which include diabetic wounds, thermal burn injuries, infected wounds, chronic wounds, and normal wounds. Kumar *et al.* (2018) studied the preparation, antimicrobial activity and clinical and commercial application of different types of biopolymer-based biomaterials in wound healing, which include collagen, gelatin, silk, keratin, natural rubber latex, chitin and chitosan, starch, pullulan, alginate, cellulose and hyaluronic acid. These materials are easy to apply on the wound site, are

Table 2 Number of clinical trials, generated from the “<https://clinicaltrials.gov>” database using the keywords (different types of biopolymers)

Keywords used	No. of studies found
Collagen	632
Gelatin	75
Silk fibroin	2
Keratin	16
Chitin	6
Chitosan	44
Starch	127
Pullulan	2
Alginate	41
Cellulose	23
Albumin	347
Casein	95
Hyaluronic acid	341
Chondroitin sulfate	34
Laminarin	1
Fucoidan	5
Sargassum	0
Carrageenan	14
Agar	4
Ulvan	0
Dextrans	26
Levan	13
Curdlan	1
Arabic gum	6
Gum kondagogu	0
Tragacanth gum	0
Xanthan gum	2
Gellan gum	0
Guar gum	5

inexpensive to fabricate and fulfil the needs of clinical expectations (Dhilip Kumar *et al.*, 2018b). Silver nanoparticle loaded chitosan, silk fibroin based biocompatible dressings showed excellent physicochemical characteristics for wound healing, and an *in vivo* mouse study revealed a positive outcome for the treatment of infected wounds (Liu *et al.*, 2017). Polysaccharide alginate, hyaluronic acid based composite materials displayed excellent wound healing effects *in vitro*, and efficiently controlled bacterial growth (Tarusha *et al.*, 2018). Cellulose matrix based nanocomposites have successfully been used for the treatment of acute and diabetic wounds. The nanocomposite based topical dressing facilitated complete wound closure with enhanced tissue repair in an *in vivo* mouse model (Singla *et al.*, 2017).

Fabrication Methodology of Biopolymer-Based Composite

There are different types of methods available to fabricate biopolymer-based composites for medical applications such as casting/solvent evaporation, freeze-drying, electrospinning, 3D printing, deposition-precipitation, nanoprecipitation, film casting, forspinning and gelation. Biofibers (chitosan solution, potato starch solution, long keratin, and ground rachis) were synthesized using the casting/solvent evaporation method. Synthesized bio composites exhibited good compatibility and the mixture of different biopolymers produced strong interactions in the matrix (Flores-Hernandez *et al.*, 2014). Nanotube-biopolymer composite scaffolds (chitosan-gelatin-agarose hydrogels doped with halloysite) were prepared by freeze – drying methods. The study showed excellent *in vitro* cell adhesion and proliferation on the synthesized material without affecting cellular viability and cytoskeleton formation. An *in vivo* rat study proved that the material promotes the formation of new blood vessels (Naumenko *et al.*, 2016).

In another study, room temperature ionic liquids was used to prepare cellulose and heparin-based composite fibers by electrospinning, and the material showed excellent anticoagulant activity (Viswanathan *et al.*, 2016). Chitosan biopolymers showed more favourable outcomes in electrospinning compared with silk, cellulose, collagen, gelatin and hyaluronic acid (Qasim *et al.*, 2018). Lam *et al.* (2002) explained the synthesis procedure of 3D porous starch-based scaffolds (cornstarch, dextran, and gelatin). The 3D printing method allows us to fabricate well-constructed novel biopolymer-based composites with good interconnected porosity (Lam *et al.*, 2002). Biopolymer-based core-shell nanoparticles were successfully synthesized using the

Table 3 Some of the major global clinical trial status of different biopolymers

<i>Name of the Biopolymer</i>	<i>ClinicalTrials.gov Identifier</i>	<i>Condition or disease</i>	<i>Intervention/treatment</i>	<i>Phase</i>	<i>Reference</i>
Collagen	NCT02767817	Brain injury	Injectable collagen scaffold with mesenchymal stem cells transplantation	Phase 1	(Injectable Collagen Scaffold™ Combined With MSCs Transplantation for Brain Injury)
Silk fibroin	NCT02091076	Impaired wound healing	Silk fibroin with bioactive coating layer dressing, Bactigras wound dressing	Phase 1 and 2	(Efficacy and Safety of Silk Fibroin With Bioactive Coating Layer Dressing)
Keratin	NCT02896725	Varicose ulcer	Keratin dressings	NA	(Wool-derived Keratin Dressings for Venous Leg Ulcers (Keratin4VLU))
Chitin	NCT01508039	Health	Chitin micro particle	NA	(Immunological Effects From Intranasal Chitin Micro-Particles (INCA))
Chitosan	NCT01278784	Dry eye syndrome	0.05% Chitosan-N-Acetylcysteine eye drops and 0.1% Chitosan-N-Acetylcysteine eye drops	Phase 1	(Local Tolerability of Chitosan-N-acetylcysteine Eye Drops in Healthy Young Volunteers)
Starch and gelatin	NCT03674684	Coagulopathy	Hydroxyethyl starch	NA	(ROTEM Assessment of Modern Crystalloid, Hydroxyethyl Starch and Gelatin Effect on Coagulation)
Pullulan	NCT00106158	Neoplasms	Protein vaccination	Phase 1	(Safety Study of NY-ESO-1 Protein Vaccine to Treat Cancer Expressing NY-ESO-1)
Alginate	NCT01338077	Gastroesophageal reflux disease	Sodium alginate	Phase 3	(Efficacy and Safety of Sodium Alginate Oral Suspension to Treat Non-erosive Gastro-esophageal Reflux Disease)
Cellulose	NCT00947089	Infections	Oxidized regenerated cellulose (Fibrillar SURGICEL)	Phase 4	(Role of Oxidized Regenerated Cellulose (ORC) Applied to “Dirty” Surgical Wounds (ORC))
Hyaluronic acid	NCT02534415	Wound healing complications – gingival graft donor site	Periodontal dressing material	Phase 4	(Effect of Topically-Applied Hyaluronic-Acid on Palatal Epithelial Wound Closure)
Chondroitin sulfate	NCT00669123	Osteoarthritis, psoriasis, joint diseases, musculoskeletal diseases, and skin diseases	Chondroitin sulfate	Phase 4	(Chondroitin Sulfate Efficacy/Safety in Patients With Knee Osteoarthritis and Psoriasis)
Fucoidan	NCT01399216	Low basal body temperature	Supplement containing fucoidan, EPA, and DHA	NA	(Effects of a Supplement Containing Fucoidan on Basal Body Temperature)
Carrageenan	NCT02382419	Healthy subject human papillomavirus infection	Carrageenan-containing gel	Phase 2	(Carrageenan-Containing Gel in Reducing the Rate of HPV Infection in Healthy Participants)
Agar	NCT02012543	Constipation	Dietary supplement: Agar jelly	NA	(Effect of Agar Administration on Defecation and Fecal Condition in Chronic Constipated Patients)
Dextrans	NCT03070353	Cirrhosis, and liver and acute kidney injury	Dextran 40	Phase 2, 3	(Dextran, a Plasma Expander, Offers New Hope for Patients With Decompensated Liver Cirrhosis and Acute Kidney Injury)
Curdlan	NCT00002100	HIV infections	Curdlan sulfate	Phase 1	(Phase I/II Study of Curdlan Sulfate)
Arabic gum	NCT03348241	Chemotherapy-induced oral mucositis	Arabic gum	Phase 2	(Using Gum Arabic for Cancer Patients to Protect From Oral Mucositis Caused by Chemotherapy: An Experimental Study)
Xanthan gum	NCT01959854	Dry eye	Carboxymethyl cellulose, xanthan gum	NA	(Efficacy of Topical 0.2% Xanthan Gum in Patients With Dry Eye)
Guar gum	NCT01779765	Irritable Bowel syndrome	Hydrolyzed Guar gum (PHGG)	Phase 4	(The Efficacy of Hydrolyzed Guar Gum (PHGG) in the Treatment of Patients With Irritable Bowel Syndrome (IBS))

deposition-precipitation method for the delivery of bioactive molecules in food and pharmaceutical formulations. The material showed good thermal stability at neutral pH, and displayed good stability free from aggregation in the pH range of 3–8 (Hu and McClements, 2015). Starch-based nanospheres was prepared using nanoprecipitation, whereby the size of the nanospheres can be easily controlled by this methodology using simple and efficient modifications. These types of nanospheres aid to load hydrophobic drugs (Tan *et al.*, 2009).

Biocomposite films (chitosan, sago starch, and silver nanoparticles) were synthesized using the method of film casting and was used as a wound dressing material. An *in vivo* wound healing study showed a faster healing pattern compared with untreated controls (Arockianathan *et al.*, 2012). Xu *et al.* (2015) developed a biocompatible biopolymer-based composite nanofiber membrane using the forspinning technique, and the materials showed synergistic antibacterial activity against *Escherichia coli*. The nanofiber membrane enhanced cell attachment and cell growth and mimics the ECM in skin. It can potentially be used for the treatment of deep and intricate wounds (Xu *et al.*, 2015). Metformin loaded bionanofiller composites were produced via the green synthesis ionotropic gelation technique using zinc acetate (cross-linker). The novel material was found to be a suitable carrier molecule for the delivery of metformin for the treatment of type 2 diabetes. An *in vivo* study in streptozotocin-induced diabetic rats showed a substantial hypoglycemic effect (Bera *et al.*, 2018).

Clinical Application and Major Global Clinical Trial Status of Biopolymers in Medical Applications

The research on biopolymer-based composites for clinical applications is considerably increasing, and the detail of the number of studies found from the “<https://clinicaltrials.gov>” database using the keywords (different types of biopolymers) are listed in Table 2. Some of the major global clinical trial status of different biopolymer-based composites are listed in Table 3.

Conclusion

Biopolymer-based composites has numerous advantages in medical applications such as the ability to act as a carrier molecule for bioactive compounds to deliver in a targeted region, high levels of biocompatibility with tissues, cells and cell compartments, good biodegradability, low immunogenicity and efficient antibacterial activity. Biopolymers derived from natural sources offers great opportunities to develop novel biopolymer-based composites and their functional applications in tissue engineering, medical implants, drug delivery systems and wound healing. Recent research and development of biopolymer-based composites has shown successful outcomes by reducing drawbacks associated with biopolymers for their use in medical applications.
